Acute Viral Hepatitis B with a Severe Clinical Course in Pregnancy: A Case Report

Gebelikte Ciddi Seyiri Akut Hepatit B: Olgu Sunumu

ABSTRACT

The most common cause of non-pregnancy-specific acute hepatitis during pregnancy is hepatitis B. The clinical course of viral hepatitis B in pregnancy is similar to that in non-pregnant women, and about 1% of patients may develop acute liver failure. In this paper, we present a patient at 16 weeks of pregnancy who was administered tenofovir disoproxil fumarate due to acute hepatitis B.

Keywords: Pregnancy, acute hepatitis B, tenofovir

ÖZ

Gebelik esnasında ortaya çıkan ve gebelikte olmayan en sık akut hepatit nedeni viral hepatit B’dir. Gebelikte viral hepatit B hastalarının klinik seyri gebeye olmayanlarla benzeri olması karşın hastaların yaklaşık %1'i akut karaciğer yetmezliğine ilerleyebilir. Bu yazımızda 16 haftalık gebeliği olan akut hepatit B hastasına takiplenen ciddi seyrî olması üzerine tenofovir disoproksil fumarat başlanan bir hasta sunulmuştur.

Introduction

Hepatitis B virus (HBV) is a DNA virus that belongs to the Hepadnaviridae family. HBV infection is an important health issue leading to acute and chronic hepatitis, cirrhosis, and hepatocellular carcinoma in clinical course (1).

Şanlıurfa is in a HBV endemic region where birth rates increase each year (2). Pregnancy-specific liver diseases are responsible for approximately 60% of the liver diseases in pregnancy, whereas 40% of these diseases are caused by acute viral hepatitis (3,4). The most common cause of jaundice is acute hepatitis B during pregnancy, and the treatment of acute infection is essentially as supportive (5). Antiviral therapy should be considered in patients with acute liver failure or severe chronic hepatitis (6). In this paper, we present a pregnant woman who was using tenofovir disoproxil fumarate due to acute hepatitis B.

Case

An 18-year-old pregnant woman was admitted to our gastroenterology department with the complaints of fatigue, yellowing of the skin, and itching. In history, she was at 16 weeks of pregnancy and itching and yellowing on her body was increased gradually in the past 2-3 days. She had no known any previous disease. Other systems were normal on physical examination. The laboratory findings were as follows: WBC: 12.300/mcL, hemoglobin: 14.4 g/dL, platelet: 258.000/mcL, urea: 8 mg/dL, creatinine: 0.5 mg/dL, aspartate aminotransferase: 2038 U/L, alanine aminotransferase: 2233 U/L, alkaline phosphatase: 183 U/L, gamma-glutamyltransferase: 45 U/L, total bilirubin: 15.4 mg/dL, direct bilirubin: 10.4 mg/dL, direct bilirubin: 10.4 mg/dL, albumin: 3.4 g/dL, prothrombin time: 18.9 seconds, international normalized ratio (INR): 1.45, activated partial thromboplastin time: 32.8 seconds, sodium: 134 mEq/L, K: 3.3 mEq/L, P: 2.6 mg/dL, and C-reactive protein: 0.87 mg/dL. Trace amounts of urobilinogen, bilirubin in urine tests: was (+ +). Patient’s viral serology were: hepatitis B surface antigen (HBsAg) (+), anti-Hbs (-), anti-hepatitis C virus (HCV) (-), anti-HBc, immunoglobulin (Ig) G (+), anti-HBc IgM (-), anti-hepatitis A virus (HAV) IgG (+), anti-HAV IgM (-), anti-HIV (-), HBV-DNA:1,27x106 IU. Ultrasonographic examination showed that the fetus was...
alive at the 16th week of gestation. The patient was hospitalized with the diagnosis of acute hepatitis B. She was hydrated and her liver function tests were monitored daily. During monitoring, there was an increase in INR and total bilirubin (2.01, 19.4 mg/dL, respectively). Hence, severe acute hepatitis B was considered and tenofovir 245 mg 1x1 was started. Because the liver function tests were decreased after treatment, the patient discharged with follow-up recommendation.

Discussion

Although pregnancy-specific liver diseases are more common in pregnant women who present with acute hepatitis, acute viral hepatitis should be considered in the differential diagnosis particularly in endemic regions (7,8). The differential diagnosis of liver diseases in pregnancy and starting treatment without delay is very important in terms of morbidity and mortality in both mother and baby. In our case, the patient had no characteristic history. The complaints of jaundice and pruritus indicated a pregnancy-specific liver disease at first. The patient’s physical examination and abdominal ultrasonography were normal except for jaundice and 1 cm hepatomegaly. Transaminases were increased more than 10-fold, and the patient was diagnosed with acute hepatitis B upon detection of HBsAg (+), anti-HBsAg (-), anti-HCV (-), anti-HBc-IgM (+), and anti-HBc-IgG (+) in the viral serology.

The treatment of acute hepatitis B is supportive (9). Acute HBV infection becomes chronic in 5-10% of adults, and approximately 1% of patients may develop acute liver failure (10). In a study, 22 pregnant women were compared with 87 non-pregnant women with acute HBV infection and no difference was found between the two groups in terms of risk of fulminant hepatic failure (11). In another study investigating the etiologic causes of fulminant hepatic failure in 52 pregnant patients, the most common cause was found to be acute hepatitis B following hepatitis E (10). Antiviral therapy should be considered in patients with acute liver failure and severe chronic hepatitis (9). Our patient was considered as having acute hepatitis B in the second trimester, and was hospitalized and followed up. In follow-up, bilirubin and prothrombin levels were increased progressively, thus, severe hepatitis B was considered and an antiviral treatment was started.

The perinatal transition rate has been reported to be 10% (12) in early acute hepatitis B, whereas this rate was reported as 60% (5) in the time of delivery. If the mother has high serum HBV DNA levels before the delivery, antiviral treatment should be considered to reduce viral load in the mother (13,14). Tenofovir disoproxil fumarate (245 mg/day) or lamivudine (100 mg/day) are considered to reduce viral load in the mother (13,14). Tenofovir was started in 3 of these patients in the last trimester because of the higher viral load (2). In our patient, severe hepatitis B was considered and tenofovir disoproxil fumarate therapy was started. Since the liver function test values were decreased after treatment, the patient discharged on follow-up recommendations.

Conclusion

Acute hepatitis B might be seen during pregnancy. These patients should be strictly followed for acute liver failure and antiviral treatment should be administered if necessary.
