Abstract

Objective: This study was conducted to compare the tocolytic efficacy of glyceryl trinitrate (GTN) with that of magnesium sulfate (MgSO4) and to investigate serum nitric oxide metabolites before and after tocolysis.

Material and Methods: In total, 48 women between 27 and 34 weeks’ gestation with threatened preterm labor and intact membranes were randomly allocated to receive either GTN or MgSO4, tocolysis. Main outcome measures included tocolytic efficacy and maternal side effect(s) of the tocolytic agent. Obstetric and neonatal outcomes as well as pretreatment and posttreatment nitric oxide (NO) metabolites were assessed.

Results: Forty-one patients were included into the final analysis. Uterine contraction cessation times were 3.66±1.28 and 6.83±3.47 hours for GTN and MgSO4 groups, respectively. Similarly, maternal side effects were significantly lower in the GTN group than in the MgSO4 group, and no serious maternal side effects were recorded. Serum NO metabolite levels before treatment were significantly lower in the treatment groups than in the controls. Serum nitrite levels were significantly increased after tocolytic treatment both in MgSO4 and GTN groups.

Conclusion: GTN effectively delays preterm delivery and reduces neonatal morbidity and mortality with less maternal side effects and seems to be an effective and safe alternative to MgSO4. (J Turk Ger Gynecol Assoc 2015; 16: 174-8)

Introduction

Preterm delivery is defined as birth before 37 completed weeks of gestation (1). Preterm birth complicates up to 10% of pregnancies and is the major cause of perinatal morbidity and mortality (2, 3). Despite advances in perinatal medicine, the incidence continues to increase (4, 5). The aim of tocolysis is to reduce neonatal morbidity and mortality by delaying birth, enabling corticosteroid administration or maternal transfer to a tertiary care center (6, 7). However, currently available tocolytics have poor efficacy and have not improved neonatal outcomes; furthermore, tocolytic agents have many maternal and fetal side effects, which generally limit their clinical usefulness (6). Human and animal studies suggest that nitric oxide (NO) is involved in the complex interplay of molecular activities, which regulate myometrial contractility (8-10). NO synthesis has been increased during pregnancy for maintaining a quiescent uterus and decreased during labor, thereby allowing uterine contractility to proceed to delivery (11-13). Some limited clinical studies have demonstrated that NO donors such as glyceryl trinitrate (GTN) can arrest preterm labor with less maternal/fetal side effects compared with other agents (14-17). However, contradictory data have been reported, stating that NO donors may have no myometrial effect or may decrease myometrial activity (18-20).

In most of these studies, GTN was compared with beta-mimetics; however, there has been no comparison of GTN with magnesium sulfate in terms of tocolytic activity and safety. The aim of the present study was to compare the efficacy and safety of GTN with those of magnesium sulfate (MgSO4) for the treatment of preterm labor.

Material and Methods

This prospective, randomized, controlled study was conducted at the Obstetrics Department of a tertiary, referral, teaching, and research hospital. The study protocol was approved by the institutional research and local ethics committee.

Study participants

In total, 48 women from 27⁰⁷weeks to 34⁰⁷weeks of gestation who were in threatened preterm labor were randomly allocated to receive either GTN (n=25) or MgSO₄ (n=23) tocolysis, and the control group consisted of 25 pregnant women who were between the same gestational age and had no signs of threatened preterm labor. Preterm labor was defined as the clinical diagnosis of at least two painful, regular uterine contractions every 10 minutes and evidence of cervical change (change in Bishop score or Bishop score>6). Inclusion criteria were single pregnancy...
with intact amniotic membrane, reassuring fetal heart rate (FHR) tracing, and no contraindication for tocolysis. Exclusion criteria included multiple pregnancy, nonreassuring FHR tracing, hypotension (blood pressure <80/50 mmHg), unexplained vaginal bleeding, placenta previa, preterm premature rupture of membranes, chorioamnionitis, cervical cerclage during present gestation, urinary system infection, maternal systemic disease, fetal growth restriction, and sensitivity or contraindication to nitrates or magnesium sulfate.

Eligible women were then approached to participate in the trial, and after final recruitment, the study protocol was explained to the patients and informed consents were obtained. The patients were randomized into two treatment groups according to software-generated random allocation sequence. The random allocation sequence was held by only one author during the entire trial period. The tocolytic drug was changed in four patients from the MgSO4 group and in three patients from GTN group, and these patients were excluded from the study in accordance with the study design (Figure 1). In conclusion, 19 patients in the MgSO4 group and 22 patients in GTN group were included in the final analysis. All the groups were matched with regard to maternal age, gestational age, and parity.

Study design
At the time of initial assessment, blood samples were collected for routine tests and serum nitrate and nitrite levels, following which maternal sedation with 10 mg intramuscular (IM) diazepam (Diazem®, Deva, Turkey) and hydration with 500 mL Ringer’s lactate and with 500 mL 5% dextrose solution were performed. Betamethasone (Celestone Chronodose®, Schering Plough, Turkey) was administered at 12 mg IM every 24 hours for a total of two doses to all the patients for promoting fetal lung development. Patients could not be treated with sedation and hydration underwent MgSO4 or GTN treatment. MgSO4 was performed; a loading dose of 6 g was given over 20 minutes, followed by an infusion of 3 g/hour. During tocolytic therapy, deep tendon reflexes, vital signs, fluid intake, and urinary output were measured hourly. Patients were followed with continuous fetal monitoring. Despite adequate blood levels of magnesium, if there was ongoing uterine activity, MgSO4 tocolysis was changed to GTN tocolysis and those patients were excluded from the study. MgSO4 treatment was continued for 12 hours after contractions had disappeared. GTN patches 0.4 mg/h (Nitroderm® 10 transdermal therapeutic system (TTS), Novartis Pharma, Turkey) were applied to the skin of the patients' abdomen. After 1 hour from the application of the patches, if there was ongoing uterine activity, a second patch was applied. At 24 hours after the initiation of treatment, the patches were removed. At 3 hours from application, if no changes were demonstrated in the uterus activity, GTN tocolysis was changed to MgSO4 tocolysis and those patients were excluded from the study. Maternal blood pressure was measured every 30 minutes for the first 3 hours and hourly thereafter after the placement of the patch. Side effects (e.g., hypotension, headache, dizziness, fatigue, tachycardia, facial flushing, itching) during the study period were recorded. Tocolytic treatment was stopped when patients experienced more severe adverse effects related to the tocolytic agent. Moderate headache was treated with paracetamol.

Bishop scores, total number of contractions in 10 minutes, the time interval between the initiation of the tocolytic treatment and resolving of uterine contractions, maternal side effect(s) of the tocolytic agent were compared between treatment groups. In addition, gestational age at delivery, mode of delivery, birth weights, Apgar scores, neonatal intensive care unit (NICU) admission, serum nitrate and nitrite levels, blood pressure, and pulse rate measurements were compared between all groups (treatment groups and controls).

Statistical analysis
All data collected were evaluated with Statistical Package for Social Sciences (SPSS, version 14, Chicago, Illinois, United States). For statistical analysis, Kruskal–Wallis, chi-square, and ANOVA tests were performed, and data were expressed as mean±SD or median±SD as appropriate. Statistical significance was defined as p<0.05.

Results
Demographic characteristics of the patients were similar in all the groups (Table 1). While pretreatment Bishop scores and total number of uterine contractions in 10 minutes were not...
significantly different between MgSO4 and GTN groups, the time interval between the initiation of the tocolytic agent and resolving of uterine contractions was significantly shorter in GTN group (3.66±1.28 hours) than in the MgSO4 group (6.83±3.47 hours). However, no significant difference was found between the treatment groups with regard to the overall prolongation of pregnancy, which is regarded as the determinant of success in the treatment of preterm delivery. This period was 37.00±21.44 days for MgSO4 tocolysis and 35.68±21.43 days for GTN tocolysis (Table 2). Although there were no significant differences between MgSO4 and GTN groups in terms of the gestational age at delivery (36.73±1.83 and 36.59±2.06, respectively) and birth weight (2810±540 and 2929±346, respectively), these parameters were significantly higher in the control group (Table 2). Apgar scores, cesarean delivery, and NICU admission rates were found to be similar between the treatment and control groups (Table 2).

Serum nitrate and nitrite levels before and after tocolytic treatment in the study and control groups are shown in Table 3. Serum nitrate and nitrite levels were significantly lower in the treatment groups than in the controls before tocolytic treatment. After tocolytic treatment, serum nitrate levels were found to be decreased in both MgSO4 and GTN groups; however, this decrease did not reach statistical significance. Although serum nitrite levels were significantly increased after tocolytic treatment in MgSO4 and GTN groups, no significant difference was found between the treatment and control groups in terms of serum nitrite levels after tocolytic therapy (Table 3). Blood pressure values after treatment were significantly lower in the treatment groups than in the control group; however, there was no statistically significant difference between MgSO4 and GTN groups with respect to decreasing blood pressures after treatment. Although the mean pulse rate was found to be significantly increased after treatment in the treatment groups, the increase in the pulse rate was greater in GTN group than in the MgSO4 group. Similarly, maternal side effects were significantly lower in the GTN group than in the MgSO4 group (Table 4). Flushing was the most frequent side effect in the MgSO4 group; however, it was not severe enough to require termination of treatment.

**Discussion**

The present study has demonstrated that GTN successfully stopped preterm uterine contractions in a shorter duration of time than MgSO4 before 34 weeks’ gestation and seemed to be

more effective than MgSO₄ when patients had more frequent contractions and required emergency tocolysis. However, the overall gestation prolongation times were similar for both GTN and MgSO₄, and this denotes that both the agents have similar tocolytic activity. Lees et al. (14) demonstrated that pregnancy was prolonged up to 34 days in 13 patients treated with 10 mg GTN despite their relative small sample size. In another multicenter study, Lees et al. (19) compared the effect of ritodrine with that of GTN and demonstrated that the mean prolongation of gestation was 36.9 days for ritodrine and 35.8 days for GTN; however, this difference was not significant. These gestation prolongation times were consistent with our results; however, in a randomized, double-blind, placebo-controlled study, Smith et al. have found that GTN patches have prolonged pregnancy for 22 days (21). This difference may have resulted from different patient selection criteria.

NO, a free radical synthesized by a family of enzymes known as NOS, is an important physiological regulator of uterine contractility (22). NO inhibits uterine contractility by various mechanisms, including the reduction of intracellular calcium levels via protein kinase C, activation of calcium pumps, and suppression of the expression of gap junctions consisting of proteins called connexin 43 (Cx43), resulting in the facilitation of action potential propagation from one cell to another (23-25). Endogenous metabolism of NO gives rise to plasma and urinary nitrite (NO₂⁻) and nitrate (NO₃⁻). The serum levels of the NO metabolites reflect NO activity in human. Nitrite is a better indicator than nitrate. Therefore, the measurement of metabolites of NO, nitrite, and nitrate in plasma/urine/amniotic fluid/vaginal secretions could be used to evaluate NO activity in humans. The reduction of serum NO metabolites levels, particularly nitrite levels, in active spontaneous preterm labor and in the active phase of induced labor at term has been shown, and it is most likely to be an indicator of a downward regulation of NO production with the onset of labor (26). The results of our study have demonstrated that serum nitrate and nitrite levels before treatment were significantly lower in the treatment groups than in the controls and serum nitrite levels were significantly higher after tocolytic treatment. Similarly, higher serum nitrite levels have been shown in patients without labor than in those with preterm or term labor (26). It may suggest that the beneficial effect of MgSO₄ and GTN on the treatment of preterm labor depends on the increase in serum NO metabolite levels.

The present study indicated significantly lower blood pressures and higher pulse rates in treatment groups. However, these findings have improved in a few hours of treatment and were not severe enough to require the termination of treatment. A randomized, double-blind, placebo trial including 74 infants born to transdermal nitroglycerin-treated mothers has indicated that transdermal nitroglycerin may reduce neonatal morbidity and mortality as a result of decreased risk of birth before 28 weeks but can cause significantly more maternal side effects (27). However, according to our results, maternal side effects were found to be significantly lower in the GTN group. It may arise from their relatively larger sample size (n=74). Although there are several reports in the literature indicating a significant decrease in the blood pressure and increase in the pulse rate after GTN tocolysis, many reports have also indicated minor changes, which do not require any interventions, in the above-mentioned vital signs (28-31).

In conclusion, in the light of our results, GTN seems to be safe, well-tolerated, and as effective as several commonly used labor-delaying medications. In addition, it has less side effects. Therefore, it may be an appropriate alternative for the treatment of preterm labor.

The limitations of our study were the small sample size and short-term follow-up period. Further trials are required to clarify this subject.

**Ethics Committee Approval:** Ethics committee approval was received for this study from the Local Institutional ethics committee of Ankara Elitik Zübeyde Hanım Training and Research Hospital.

**Informed Consent:** Written informed consent was obtained from patients who participated in this study.

**Peer-review:** Externally peer-reviewed.
