Abstract

Objective: To investigate the relationship between specific endothelial nitric oxide synthase (eNOS) gene polymorphisms and endometrial cancer (ECa).

Material and Methods: The study group consisted of 89 patients histologically diagnosed with the endometrioid type of endometrial carcinoma. The control group consisted of 60 randomly selected individuals who had undergone total hysterectomy. Genomic DNA was isolated from paraffin-embedded endometrial tissues. We investigated the G894T polymorphisms (G894T) and variable number tandem repeats polymorphisms in intron 4 (VNTR intron 4) in the eNOS gene by using polymerase chain reaction (PCR) and/or restriction fragment length polymorphism (RFLP). The genotype distributions and allele frequencies of the two groups were compared.

Results: Analysis of the VNTR intron 4 polymorphisms in eNOS gene revealed that the frequency of the AA genotype was significantly higher in the control group, whereas the frequency of the BB genotype was significantly higher in the ECa group. Analysis of the G894T polymorphisms in eNOS gene revealed a significantly higher frequency of the GG genotype in the control group but a significantly higher frequency of the TT genotype in the endometrial cancer group.

Conclusion: The G894T and VNTR intron 4 polymorphisms in eNOS gene could be an intriguing susceptibility factor that modulates an individual’s risk of ECa in the Turkish population.

Key words: eNOS gene polymorphisms, endometrial carcinoma

Introduction

Endometrial cancer (ECa) is the most common pelvic malignancy. Each year, ECa develops in about 142,000 women worldwide and approximately 42,000 women die because of ECa (1). The majority of these tumors are of the endometrioid type that are typically hormone sensitive and have an excellent prognosis. Although hormonal and genetic association studies have been performed, the pathophysiology of ECa is still unclear (2-4).

Nitric oxide synthase (NOS), which has three isoforms, catalyzes the oxidation of L-arginine to nitric oxide (NO) and citrulline. Endothelial nitric oxide synthase (eNOS) is one of three isoforms of NOS that generates NO in vascular endo-
The eNOS gene is encoded by the eNOS gene which was localized to chromosome 7q35-36 (5). The eNOS gene have about 1,500 base pairs of upstream promoter sequence similar to other NOS and include transcription factor-binding sites that mediate regulation by estrogens, shear stress and other cofactors (6). Under normal physiological conditions, constitutively expressed NO is a very important intercellular messenger molecule. However, high concentrations of metabolic products of NO have been implicated in mutagenesis and carcinogenesis (7). Potentially cytotoxic oxygen and nitrogen metabolites of NO may directly damage DNA bases, resulting in point mutations, strand breaks and interactions with sulfhydryl groups, leading to carcinogenesis. Some of these metabolites can react with secondary amines and N-alkylamides to form nitroamines, which have been implicated in human carcinogenesis (8). Despite these negative effects on carcinogenesis, endothelial production of nitric oxide regulates blood flow and angiogenesis and reduces tumor cell adhesion to the endothelium and so positively affects tumor pathogenesis (9).

Recently, association studies on eNOS gene polymorphisms with different types of cancer including vulvar, prostate, colorectal and breast cancer have been demonstrated (10-13). Based on these data, the present study aimed to determine the relationship between eNOS gene polymorphisms and ECa. Although studies on Single Nucleotide Polymorphisms (SNPs) involved in DNA damage repair, steroid metabolism, carcinogen metabolism, cell-cycle control, apoptosis and steroid receptor activation pathways in ECa were performed, this is the first study in the English literature (14-18).

Based on these data, the present study aimed to determine the relationship between eNOS gene polymorphisms and ECa. Although studies on Single Nucleotide Polymorphisms (SNPs) involved in DNA damage repair, steroid metabolism, carcinogen metabolism, cell-cycle control, apoptosis and steroid receptor activation pathways in ECa were performed, this is the first study in the English literature (14-18).

Although extensively different eNOS gene variants have been demonstrated, functional variation in the eNOS gene has yet to be completely characterized (19). This study has focused on two functional variants: a variant G to T conversion at nucleotide position 894 resulting in the replacement of glutamic acid with aspartic acid at codon 298 (G894T) and a variant variable number of 27 bp tandem repeats in intron 4 (VNTR intron 4) in a Turkish population.

Materials and Methods

Patients and Controls

The study was designed as a retrospective study. Formalin-fixed (10% neutral buffered formalin), paraffin-embedded surgical materials obtained between the years 2000 and 2010 were selected from the archives of the Department of Pathology of Gaziantep University Faculty of Medicine. The study group consisted of 89 patients histologically diagnosed with the endometrioid type of ECa. The control group consisted of 60 randomly selected individuals who had undergone total hysterectomy because of postmenopausal benign adnexal pathologies, dysfunctional uterine bleeding or myoma uteri at Gaziantep University. Hematoxylin and eosin-stained sections from each case were reviewed and representative sections for each case were selected. Genomic DNA was isolated from paraffin-embedded endometrial tissues. This study was approved by the local ethics committee of Gaziantep University. The patients were diagnosed with ECa by fractional endometrial biopsy. Thereafter, total abdominal hysterectomy, bilateral salpingoophorectomy, bilateral pelvic and para-aortic lymphadenectomy, omentectomy, and peritoneal fluid sampling were performed in all ECa patients. Histopathological diagnosis and surgical staging were established according to the International Federation of Gynecology and Obstetrics (FIGO) criteria (20). All patients were operated by the same team of surgeons and all slides were reviewed by the same pathologist.

Genotyping

We investigated the following two polymorphisms of the eNOS gene: the G894T polymorphisms; and the VNTR polymorphisms in intron 4. Genomic DNA was isolated from paraffin-embedded endometrial tissues (21). In order to analyze the G894T polymorphisms, polymerase chain reaction (PCR) was used to amplify a 206-bp fragment. The resulting fragment was digested with MboI restriction endonuclease (Invitrogen CA, USA) overnight at 37°C. Digestion was resolved on a 3% agarose gel and visualized under ultraviolet light. For the analysis of the VNTR polymorphisms in intron 4, primers were designed to amplify a 393-bp and/or 420-bp segment of the polymorphic VNTR region containing the microsatellite repeat sequence. The products were then separated on 3% agarose gel (Figures 1, 2) (21, 22).

Statistical analysis

Statistical Package for the Social Sciences (SPSS) for Windows (version 9.0; SPSS Inc., Chicago, IL, USA) was used for statistical analysis. Results were expressed as mean±standard deviation. Analysis of data regarding age was performed using the Student’s t-test. A chi-square test was used to compare the two groups with...
respect to the genotype distributions and allele frequencies. The Hardy-Weinberg equilibrium (HWE) was calculated using the Finetti programme provided as an online source (23). Analysis of variance (ANOVA) and Kruskal-Wallis test were performed to compare genotypes of VNTR intron 4 or G894T polymorphisms in eNOS gene according to age and histopathological grade. A p value of <0.05 was considered statistically significant.

Results
The mean age in the ECa and control groups was 62.4±1.2 and 64±0.3, respectively. There were no significant differences between the ECa and control groups with respect to age (p=0.89).

In the patient group; of 89 patients, 74 (83.1%) were stage I, 7 (7.86%) were stage II, and 8 (10.0%) were stage III cancer patients. Of all patients, 39 (43.8%) had grade 1 (well-differentiated), 30 (37.8%) had grade 2 (moderately differentiated), and 20 (22.4%) had grade 3 (poorly differentiated) tumors.

The distribution of genotypes and allele frequencies are shown in Table 1 and Table 2. Regarding the VNTR intron 4 polymorphisms, while there was no deviation from HWE in control and patient groups, a significant difference existed between the two groups with respect to the genotype distribution. Comparison of the two groups revealed that the frequency of the AA genotype was significantly higher in the control group, while the frequency of the BB genotype was significantly higher in the ECa group (p=0.015 and p=0.015, respectively).

Regarding the G894T polymorphisms, there was a significant difference between the two groups with respect to the genotype distribution. There was no deviation from HWE in patient and control groups. Comparison of the two groups revealed a higher frequency of the GG genotype in the control group, whereas there was a significantly higher frequency of the TT genotype in the ECa group (p=0.003 and p=0.003, respectively).

No correlation was observed between patient age or histopathological grade and genotypes for the VNTR intron 4 polymorphisms (p=0.991, p=0.719) and for the G894T polymorphisms (p=0.560, p=0.178).

Discussion
Although ECa is the most common gynecologic cancer worldwide and numerous studies have been performed on risk factors or prognostic factors, the underlying carcinogenic mechanisms remain unknown (24, 25). Unopposed and prolonged estrogen stimulation, including stimulation by nulliparity, late menopause, and obesity, has been identified as a risk factor for the development of ECa. Estrogen acts in two different ways in the carcinogenesis of ECa; as a hormone that stimulates cell proliferation and as a procarcinogen that induces genetic damage by the action of free radicals. Cellular and molecular vascular studies demonstrated the estrogen-induced rapid, membrane-initiated activation of numerous signal transduction cascades (26). These effects include estrogen-stimulated, rapid activation of eNOS, resulting in

production of NO which has implications in carcinogenesis, tumour progression, invasion, angiogenesis and modulation of therapeutic responses (27, 28).

In the literature, several SNPs of the eNOS gene have been reported in various cancers with increased risk of developing malignancy (11, 29) and prognosis after developing malignancy (30, 31); however, there is no study in the literature investigating the relationship of SNPs of the eNOS gene with ECa. Recently, Hao et al. performed a meta-analysis about G894T polymorphisms of eNOS gene in breast cancer which has similar risk factors such as nulliparity, late menopause, and obesity to ECa (11). They concluded that there was a significant association between the eNOS polymorphism and the risk of breast cancer. The result of our study on G894T polymorphisms of eNOS gene in ECa suggest that, while the homozygote T variant of G894T polymorphisms in eNOS could be a predisposing factor for ECa, the homozygote G variant could be a protective factor for ECa in Turkish population.

In the literature, only a few case-control studies have been performed to evaluate the role of intron 4 polymorphisms in cancer. Although VNTR intron 4/eNOS variant is less likely to be functional, recently Yeh et al. demonstrated the association between VNTR intron 4/eNOS polymorphisms and early-onset colorectal cancer (13). In this study, we observed the association between VNTR intron 4/eNOS polymorphisms and ECa. To the best of our knowledge, this is the first report of a relationship between eNOS gene polymorphisms and ECa. In conclusion, Glu298Asp and VNTR intron 4 polymorphisms in the eNOS gene could be an intriguing factor that modulates an individual’s risk of ECa in Turkish population. However, further studies with a large number of patients to clarify the association between eNOS gene polymorphisms and risk of developing ECa and to evaluate the relationship between prognosis in ECa and eNOS gene polymorphisms are needed.
