Abstract

Playing a key role in the pathophysiology of many diseases, A Disintegrin-like and Metalloproteinase with Thrombospondin type-1 motif (ADAMTS) proteinases have been attracted more attention in obstetrics and gynecology. First discovered in 1997, this zinc-dependent proteinase family has 19 members today. These enzymes, which are located in the extracellular matrix (ECM), have a lot of very important functions, like matrix formation and resorption, angiogenesis, ovulation, and coagulation. In addition, in the pathogenesis of cancer, inflammation, arthritis, and connective tissue diseases, ADAMTS proteinases have crucial roles. The purpose of this review is to collect previous studies about obstetrics and gynecology that are related to ADAMTS enzymes and discuss the subject in many aspects to give an idea to the investigators who are interested in the subject. (J Turk Ger Gynecol Assoc 2014; 15: 250-5)

Key words: ADAMTS, reproductive diseases, biological marker

Introduction

A Disintegrin-like and Metalloproteinase with Thrombospondin type-1 motif (ADAMTS) proteinases, which are released outside the cell (soluble), have very critical roles in damage and repair of extracellular matrix (ECM) processes (remodeling) (1). The ADAMTS family, which degrades ECM structural substrates, such as collagen, aggrecan and versican, has 19 family members (2). These enzymes, which are associated with a great deal of vital physiological processes in the ECM, are inhibited by tissue inhibitors of metalloproteinases (TIMPs) (3, 4). Family members of this group are divided into various subgroups according to their tasks in the ECM (Figure 1).

ADAMTS1 (METH-1), which was identified for the first time in colon adenocarcinoma, is associated with inflammation (5) and shows anti-angiogenic properties with ADAMTS8 (METH-2) (6, 7). Especially in the physiology of ovulation, there is interest in these proteases. ADAMTS1 also takes important roles in the process of normal growth, fertility, and organogenesis (8). ADAMTS 2, 3, and 14, also known pro-collagen N-proteinases, have important roles in collagen synthesis in the ECM. Various connective tissue diseases are seen in ADAMTS2 deficiency in this group (9). ADAMTS1, -4, -5, -8, -9, -15, -16, and -18 degrade aggrecan, which is the one of the main components of the ECM; so, they are called as aggrecanases (1). ADAMTS1, -4, and -5 degrade brevican and versican, other structural ECM components (10). Versican helps hyaluronan, which is the basic element of the ECM, to stabilize the matrix (11). ADAMTS5 and -6, expressed specifically in the placenta, are thought to be responsible for implantation (12). ADAMTS7 and -12 degrade Cartilage oligomeric matrix protein (COMP), which is an essential glycoprotein in cartilage matrix (13). ADAMTS10 has important roles in the development of tissues of skin and lens. In ADAMTS10 mutations, autosomal recessive Weil-Marchesani syndrome is seen (14).

Known as von Willebrand cleaving protease, ADAMTS13 has effects on coagulation and homeostasis. This protease degrades ultralarge VWF multimers that are localized in endothelial surfaces; so, it prevents thrombus formation (9). Thrombotic thrombocytopenic purpura (TTP), a serious problem during pregnancy, occurs in ADAMTS13 deficiency (15). Increased by follicle-stimulating hormone (FSH) and luteinizing hormone (LH), ADAMTS16 degrades a-2 macroglobulin in the ECM (16). ADAMTS17 is involved in estrogen-induced apoptosis in cancer cells (16). ADAMTS9 and -20 are known...
as Gon-ADAMTS (17). ADAMTS10 and ADAMTS19, whose roles are unknown today, are called orphan ADAMTS proteinases (1).

**ADAMTS in the Physiology of Obstetrics and Gynecology**

**Ovarian physiology and ADAMTS**

For successful ovulation, cumulus oocyte complex (COC) formation and rupture of ovarian surface epithelium must occur properly (18). While COC formation occurs, the synthesis of basic ECM components, like versican and hyaluronic acid (HA), is increased (18). The synthesis of proteoglycans, such as aggrecan, versican and brevican, which bind to HA, increases in the ovaries after an LH surge (10, 19). These proteoglycans are basic components of the ECM, together with HA. Versican, a substrate of ADAMTS1, -4, and -5, has roles in ECM remodeling, movement of cumulus cells, and maintaining the structural and functional integrity of the matrix (10, 18). In the peri-ovulatory period, ADAMTS1, -4, and -5 degrade versican, resulting in the expansion of the COC (18, 19). For successful ovulation, this destruction must occur (10, 16, 17).

Progesterone (PG) and its receptor (PR) are two genes that are activated by LH in ovaries. PG binds to receptors (PGR) on the granulosa cell resulting in increased ADAMTS1 (8, 9, 20, 21) (Figure 2). In disorders of PR, which controls expression of progesterone receptor (PG-R) in granulosa cells. Progesterone leads to increased expression of ADAMTS1, which is responsible for the degradation of proteoglycans, like syndecan and perlecain, in the ECM, is increased by gonadal steroids, such as PG, estrogen, and androgens (28, 29). ADAMTS1, responsible for ECM remodeling, also has critical roles in the initiation and successful maintenance of decidualization (29). In ADAMTS1 knockout mice, the uterus develops, but successful implantation and placental development (28). ADAMTS1, one of the considerable structures that are responsible for these changes, is effective in all uterine tissues throughout the menstrual cycle (12). ADAMTS1 has a role in matrix remodeling. The expression of ADAMTS1, which is responsible for the degradation of proteoglycans, like syndecan and perlecain, in the ECM, is increased by gonadal steroids, such as PG, estrogen, and androgens (28, 29). ADAMTS1, responsible for ECM remodeling, also has critical roles in the initiation and successful maintenance of decidualization (29). In ADAMTS1 knockout mice, the uterus develops, but successful implantation does not occur (12, 28).

**Menstrual cycle and ADAMTS**

Various structural changes in the endometrial ECM are seen in the menstrual cycle. These changes are quite important for successful implantation and placentation (28). ADAMTS1, one of the considerable structures that are responsible for these changes, is effective in all uterine tissues throughout the menstrual cycle (12). ADAMTS1 has a role in matrix remodeling. The expression of ADAMTS1, which is responsible for the degradation of proteoglycans, like syndecan and perlecain, in the ECM, is increased by gonadal steroids, such as PG, estrogen, and androgens (28, 29). ADAMTS1, responsible for ECM remodeling, also has critical roles in the initiation and successful maintenance of decidualization (29). In ADAMTS1 knockout mice, the uterus develops, but successful implantation does not occur (12, 28).

**Figure 1. ADAMTS tree: Classification of ADAMTS proteinase according to their functions**

**Figure 2. Luteinizing hormone (LH) secreted from the pituitary gland, increases secretion and expression of progesterone and progesterone receptor (PG-R) in granulosa cells. Progesterone leads to increased expression of ADAMTS1 by binding to its receptors (PG-R) on the granulosa cells. ADAMTS1 degrade versican. This degradation causes to expand COC formation and ovulation (8, 9, 20, 21)**
the synthesis of these proteases result in infertility (36).

These enzymes, which have critical roles in endometrial physiology, lead to decidualization in the endometrium. Defects in the expression of ADAMTS5, -8, and -9 in endometrium cell culture.

Gonadal steroids, like PG and dihydrotestosterone, regulate the expression levels of ADAMTS5, -15 are expressed at very high levels, especially in the first trimester, it was shown that ADAMTS12, independent of other metalloproteinases, was responsible for the invasion of trophoblastic cells. The expression of this protease is regulated by IL-1β and TGF-β1, like ADAMTS1 and -5. ADAMTS12 also regulates cell-ECM adhesion and invasion (39).

In placental tissue samples taken from pregnant women in the first trimester, it was shown that ADAMTS12, independent of other metalloproteinases, was responsible for the invasion of trophoblastic cells. The expression of this protease is regulated by IL-1β and TGF-β1, like ADAMTS1 and -5. ADAMTS12 also regulates cell-ECM adhesion and invasion (39).

Menopause and ADAMTS
Menopause is an important physiological event closely related to women’s health. Genetic studies have showed that various genes are associated with menopause. ADAMTS9 is one of these genes. The relationship between the ADAMTS9 and SMAD3 genes is associated with natural menopause age (40). Bone mineral densitometry (BMD), an examination method to determine osteoporosis, is influenced by several genetic and environmental factors. Although the peak level of BMD is influenced by diet and physical activity, genetic factors are also important. Studies about this issue showed that ADAMTS18 has been associated with femoral neck bone mineral density (41).

Thrombotic thrombocytopenic purpura/other diseases that are predisposed to thrombosis and ADAMTS
Thrombotic thrombocytopenic purpura is a rare disease associated with thrombocyte aggregation secondary to thrombocytopenia, hemolytic anemia, and ischemic conditions. In TTP, which is an acute onset and quite fatal disease, there are hyaline thromboses in a great deal of tissue and organs (42). Although it is a rare disease, its incidence increases during pregnancy (43, 44). In the pathogenesis of the disease, ultralarge von Willebrand factor multimers, which must be degraded by ADAMTS13 (vWFCP) in circulation, have an essential role (42). This disease is more frequently seen in pregnancy. Pregnancy-related hypercoagulability and decline of ADAMTS13 levels are the reasons (45). Especially in severe ADAMTS13 deficiency, TTP develops during pregnancy (46). The risk of recurrence after pregnancy is high. For this reason, early diagnosis and treatment of TTP are needed (43).

In ADAMTS13 deficiency, the incidence of HELLP, preeclampsia, and hemolytic uremic syndrome (HUS) also increases (43). In HELLP syndrome (hemolysis, elevated liver enzymes and low platelet count), active plasma vWF levels and the propeptide/mature vWF ratio have been found to be higher than in normal pregnancy and preeclampsia. ADAMTS13 levels have been also found to be low (47). In the pathogenesis of HELLP syndrome (hemolysis, elevated liver enzymes and low platelet count), there is thought to be acute endothelial activity, like TTP (47).
Early diagnosis and treatment of TTP in pregnancy are crucial. Measurement of ADAMTS13 levels is helpful in the diagnosis. An ADAMTS13 level of no less than 5% or the absence of ADAMTS inhibitors, and expression of ADAMTS gene mutations will help confirm the diagnosis (48).

**Polycystic ovary syndrome (PCOS) and ADAMTS**

Polycystic ovary syndrome is a common disease that affects mostly women of reproductive age. In this disease, common cysts in the ovaries, oligo-anovulation, hyperandrogenism, hyperinsulinism and insulin resistance are seen. Abnormal steroidogenesis/folliculogenesis and developmental disorders in the dominant follicle result in impairment of ovarian function. The expression of ADAMTS1 is reduced in PCOS. This is thought to be associated with the failure of ovulation, impairment of oocyte quality, and declined fertilization rate (49).

**Premature ovarian failure (POF) and ADAMTS**

Premature ovarian failure, one of the most important diseases that cause female infertility, is a disease characterized by amenorrhea occurring before the age of 40 and hypergonadotropic hypogonadism. In the development of POF, the dysfunction and destruction of follicles are important physiological events. In genomic studies, ADAMTS19 has a role in ovarian development. It is thought ADAMTS19 may be important in the pathogenesis of POF (50, 51). Insulin-like growth factor (IGF-2) increases the number of FSH receptors in granulosa cells. IGF-2 and FSH induce steroidogenesis in these cells. IGF-2 is a useful marker to identify high-risk POF patients. In the pathogenesis of POF, there is a relationship between ADAMTS19 and IGF-2 receptors (50).

Activin A is an effective hormone that provides germ cell proliferation and survival in ovaries. In the pathogenesis of POF, there is a relationship between ADAMTS19 and activin type II receptors (ACVR2) (52). Thyroid-stimulating hormone (TSH) induces steroidogenesis induced by gonadotropin. In thyroid dysfunctions, estrogen metabolism disorders, menstrual disorders and infertility are seen. In previous studies, there was a relationship between ADAMTS16 and the TSHβ gene. This relationship is associated with POF pathogenesis (53).

**Gynecologic cancers and ADAMTS**

Endometrial adenocarcinoma composes 80% of endometrial cancers, which are the most frequently seen gynecologic cancers in women. In these tumors, while angiogenesis increases, invasiveness also increases. ADAMTS1 plays an important role in invasiveness associated with tumor cell migration and metastasis. Increased in endometrial adenocarcinomas, ADAMTS1 is related to epithelial cell invasion and endothelial cell function (54). ADAMTS4 and -5 are highly expressed in gestational trophoblastic diseases. These proteases are closely related to the biological behavior of gestational trophoblastic disease. It is suggested that the staining pattern of these proteases may help make the distinction between normal gestation, early complete mole, invasive mole, and choriocarcinoma (31).

Epithelial ovarian cancer composes 90% of ovarian cancers, which are the most disastrous gynecologic cancers in women. Several epigenetic changes were detected in these tumors. Methylation of DNA is one of these epigenetic mechanisms. The activity of hypermethylated genes reduces. Although HOXA9, HOXB5, CRABP1, and SCGB3A1 have been shown to be hypermethylated in ovarian carcinomas, the ADAMTS1 gene is not methylated (55).

**Conclusion**

We tried to point out the importance of ADAMTS proteinases, which have been hugely popular in recent years, in obstetrics and gynecology. These enzymes have very critical roles in the physiology of the female reproductive system, including ovulation and the pathogenesis of obstetric and gynecology diseases (56) (Figure 3). There are not enough studies about this subject in obstetrics and gynecology. A great deal of studies are required to analyze the ADAMTS gene promoter, discover signaling pathways and point out single-nucleotide polymorphisms (1). In these studies, the functions of this family, in the ECM context will be studied in the female reproductive system, like other tissues and organs.
