The Effect of Vitamin D Deficiency on the Severity of Bronchiolitis in Infants

Süt Çocuklarında Vitamin D Eksikliğinin Bronşiolit Ciddiyeti Üzerine Etkisi

ABSTRACT

Aim: This study was conducted to investigate the effect of vitamin D deficiency on the severity of bronchiolitis in infants who were hospitalized for treatment.

Materials and Methods: The infants who were followed up in our hospital and monitored due to acute bronchiolitis within a 0 to 24-month period were included in the study. The cases were evaluated by the clinical characteristics scoring system and divided into two groups (mild and moderate-severe). A questionnaire filled in by the mothers of the children to question the factors associated with vitamin D. The vitamin D levels of the cases, their clinical histories, and histories of taking vitamin D were examined.

Results: The number of patients with a vitamin D level <20 ng/mL in the moderate-severe disease group was higher than the number in the mild disease severity group (p<0.05). No difference was detected in the number of patients who received vitamin D prophylaxis between the moderate-severe and mild disease severity groups (p>0.05). The number of patients with vitamin D level <20 ng/mL was higher in the hospitalized group than in the non-hospitalized group (p<0.05). There was no difference in the number of patients that received vitamin D prophylaxis between the hospitalized and the non-hospitalized groups (p>0.05).

Conclusion: Vitamin D deficiency in infants is associated with increased severity of bronchiolitis and hospitalisation.

Keywords: Bronchiolitis, vitamin D deficiency, infant

ÖZ

Amaç: Bu çalışma, bronşiyolit nedeniyle hastaneye yatırılarak tedavi edilen süt çocuklarında vitamin D eksikliğinin bronşiyolit ciddiyetine üzerine etkisinin araştırılması amacıyla yapılmıştır.

Bulgular: Orta ve ağır derecedeki hastalık grubunda D vitamini düzeyi <20 ng/mL olan hastaların sayısı hafif gidişte hastalık grubundakilerinden sayısından daha yüksekkti (p<0,05). Hafif derecedeki hasta grubu ile orta-ağır derecedeki hasta grubunda D vitamini profilaksi alinan hastaların sayısı arasındaki anlamlı farklılık saptanmamı (p>0,05). Hastaneye yatırılan hastalararasında D vitamini düzeyi <20 ng/mL olan hastaların sayısı hastaneye yatışın grupta artışa ve hastane boyunca hastaneye yatışın grupsın arasında anlamsız fark saptanmamı (p>0,05).

Sonuç: Süt çocuklarında D vitamini eksikliği, artmış bronşiyolit gidişti ve hastaneye yatış ile ilişkilidir.

Anahtar Kellimeler: Bronşiyolit, D vitamini eksikliği, süt çocuk

Introduction

Recently, the harmful effects of pathogens that cause bronchiolitis have strengthened, possibly due to increasing rates of vitamin D deficiency within infants. Vitamin D has been demonstrated to play roles in both immune system activation and the prevention of infections by microorganisms. An increased risk of respiratory system
diseases has been demonstrated in the first three months in infants with low vitamin D levels in the cord blood at birth (1). Recent studies have defined vitamin D deficiency as a serum 25-hydroxyvitamin D [25(OH)D] level equal to or less than 20 ng/mL, whereas vitamin D insufficiency is defined as a serum level between 21 and 29 ng/mL. The lowest 25(OH) D level that will not activate parathormone is 30 ng/mL (75 nmol/L), therefore, a sufficient vitamin D level is accepted as >30 ng/mL (75 nmol/L) (2-4). Vitamin D effects susceptibility to infections that trigger wheezing at an early age and the response to this process. The relationship between serum vitamin D levels and respiratory tract infections was shown in the National Health and Nutrition Examination Survey (NHANES) III study, where this relationship was more evident in patients with asthma and chronic obstructive pulmonary disease (5). In another population-based study, a strong relationship was found between vitamin D serum levels and forced expiratory volumes in 1 second (6). Respiratory tract infections are frequent causes of asthma exacerbation among children and adults, and are associated with low vitamin D levels (7). The most frequently reported factors that result in exacerbation are rhinoviruses and corona viruses (8). In a recent study, vitamin D serum levels were shown to be inversely related to the total immunoglobulin E concentration and eosinophil numbers, and hospitalizations were rarer among patients with high vitamin D levels during the preceding one year period. The relationship between a high vitamin D level and a decrease in the need for anti-inflammatory treatment was shown in the same study (9).

Materials and Methods

Study Population

This single center prospective study was conducted at Bağcılar Training and Research Hospital, Clinic of Pediatrics in Istanbul, Turkey between January and April 2015.

Bronchiolitis was diagnosed in children aged 1-24 months in accordance with the study’s inclusion criteria; a total of 102 children receiving treatment at the hospital were included. Children with known chronic lung disease, heart disease, recurrent lower respiratory tract infection, growth retardation, and a history of premature birth were excluded. The diagnosis of bronchiolitis was made during the medical examination of the patients, with regard to complaints of coughing, and respiratory distress alongside clinical findings such as rales and rhonchi.

The patient data were obtained from the history and file records. The history of bronchiolitis, history of hospitalization, use and duration of vitamin D prophylaxis in infancy were recorded according to the information obtained from the mother. The assessment of disease severity was determined in accordance with the Turkish Thoracic Society guidelines for acute bronchiolitis (10). The patients were divided into two groups (mild and moderate-severe) according to their clinical conditions. The classification was based on the general condition of the patient, breaths per minute, the presence of apnea, pulse rate, oxygen saturation and the existence of chest retraction (Table I).

The questionnaire forms were prepared. The form was filled in according to the definitions of the mothers during examination. The results of these questionnaire forms were given in Table II. Infants who had used vitamin D or vitamin preparations containing vitamin D for more than six months were accepted to have used vitamin D regularly.

Laboratory Measurements

Blood samples were taken from all the infants to study the serum vitamin D levels. The blood was centrifuged for 5 minutes at 3000 rpm, and the serum was separated. Each serum sample was covered with dark carbon paper to prevent light permeation and then frozen and stored at -30 degrees C prior to the analysis. The vitamin D levels were examined using the electro chemiluminescence enzyme immuno assay method (ADVIA Centaur, USADPC Co., USA).

The study protocol was approved by the Research Ethics Committee of Bağcılar Training and Research Hospital in accordance with the Declaration of Helsinki (approval number: 2014-300). Informed consent was obtained from the parents of all study participants.

Statistical Analysis

The mean, standard deviation, median lowest and highest values, frequency and ratio values were used as the descriptive statistics of the data. The distribution of the variables was measured using the Kolmogorov-Smirnov test. The Mann-Whitney U test was used in the analysis of the qualitative data together with the chi-square; when the chi-square test conditions were not met, Fisher’s test was used. The Spearman correlation analysis was used to assess correlations.

Results

The demographic data from the infants included in the study are presented in Table II. No significant difference in disease severity was detected between the groups in terms of gender and age distribution. The vitamin D concentration
was significantly lower in the moderate-severe group. The number of patients with vitamin D concentrations <20 ng/mL in the moderate-severe disease group was higher than the number in the mild disease severity group. No difference was detected in the number of patients who received vitamin D prophylaxis between the moderate-severe and mild disease severity groups (Table III).

The number of patients between 0 and 2 years of age was higher in the hospitalized group compared to the non-hospitalized group. There was no difference in the gender distribution between the hospitalized and non-hospitalized groups, but the vitamin D concentration was lower in the hospitalized group. The number of patients with vitamin D concentrations <20 ng/mL in the hospitalized group was higher than that in the non-hospitalized group. No difference was detected between the rates of patients that received vitamin D prophylaxis in the hospitalized and non-hospitalized groups. There was no significant correlation between the vitamin D level and the hospitalization durations and patient age. The gender distribution and age distribution were not significantly different between the moderate-severe and mild disease severity groups. However, the vitamin D concentration was significantly lower in the moderate-severe disease severity group (p<0.05). The number of patients that received vitamin D prophylaxis was not significantly different between these two groups. The vitamin D concentration was significantly lower in the hospitalized group than in the non-hospitalized group (p<0.05).

### Discussion

Vitamin D plays a role in immune system activation, it helps to prevent infections caused by microorganisms. Studies have shown a relationship between the severity of bronchiolitis, increased hospitalization, and vitamin D deficiency (11). In this study, we investigated the relationship between vitamin D deficiency and bronchiolitis severity, and found that vitamin D levels are very important for infants with bronchiolitis.

Many studies have proposed that vitamin D concentration decreases due to the decrease in sunlight during the winter months, resulting in a related decrease in immune functions and sensitivity to influenza infections (12,13).

The study by Mansbach and Camargo (12) showed that the wheezing rate was increased in infants of mothers who had vitamin D deficiency during pregnancy. An increased risk of respiratory system diseases was observed in the first three months in infants with low vitamin D concentration in the umbilical cord blood (14).

In the hospital-based case control study performed by Wayse et al. (15), the authors concluded that insufficient breast milk intake and subclinical vitamin D deficiency in the first 4 months of life constituted a significant risk factor for severe lower respiratory tract diseases.

Infections are the most frequent causes of morbidity and mortality among children worldwide. The relationship between insufficient vitamin D levels and respiratory tract infections in children and/or hospitalization has been shown...
in many epidemiological studies. Najada et al. (16) also reported a high incidence of nutritional rickets among infants hospitalized due to respiratory tract diseases.

In this study, the rate of the patients between the ages 0 and 2 years was significantly higher in the hospitalized group than in the non-hospitalized group. The gender distribution did not exhibit significant differences between the hospitalized and non-hospitalized patients. The vitamin D concentration was significantly lower in the hospitalized group, but the number of patients with vitamin D <20 ng/mL in this group was significantly higher than in the non-hospitalized group. The number of patients that received vitamin D prophylaxis in the hospitalized and non-hospitalized groups was not significantly different.

According to the NHANES data, the frequency of upper respiratory tract infections in patients with serum vitamin D <25 nmol/L was much higher in patients with asthma compared to those without (5). The relationship between vitamin D and asthma has been known for a long time. Although the mechanism is not known, new studies have found an association between high vitamin D levels and better lung functions, lower respiratory tract hypersensitivity and increased glucocorticoid responses (17).

In a case-control study, the vitamin D level in newborns taken to the intensive care unit due to lower respiratory tract infections was demonstrated to be significantly lower compared to healthy infants in the same age group. Additionally, the vitamin D concentration of the mothers was lower compared to the control group (18).

The mechanism by which vitamin D affects the immune system is not known. Viral infections are observed more frequently than bacterial infections in patients with vitamin D deficiency. Therefore, the relationship between vitamin D and immune functions shows the importance of supplementation in the pediatric population (19). In another study performed by Karatekin et al. (20), vitamin D concentrations were examined in the sera of newborns that did not have rickets with a lower respiratory tract infection (LRTI) diagnosis and their mothers. Based on the results, the risk of damage due to LRTI was increased in newborns with a subclinical vitamin D deficiency. The strong positive correlation between the vitamin D concentrations of the newborns and their mothers showed that sufficient vitamin D supplementation should be emphasized during pregnancy in winter months (19,20).

A large number of studies have proposed that vitamin D reduces the risk of respiratory tract infections in children (13). In one study, a 13-fold higher risk was found in Ethiopian children younger than 5 years of age whose vitamin D deficiency was shown clinically (21). In a study performed in Yemen, a 50% vitamin D deficiency was found in children who were admitted (22).

The gender and age distributions were not significantly different in the moderate-severe and mild disease severity groups in this study, but the vitamin D concentration was significantly lower in the moderate-severe disease group. Also the number of patients with vitamin D level <20 ng/mL in this group was significantly higher. There was no significant difference in the number of patients who received vitamin D prophylaxis between the two groups.

Studies have demonstrated a role for vitamin D in the expression of the human cathelicidin antimicrobial peptide, which plays a role in host defense against respiratory tract pathogens. These studies showed that the risk of respiratory system infection was increased in subjects with vitamin D deficiency. This increased risk contributes to the increase in the wheezing incidence in children and the exacerbation of asthma in adults. Vitamin D plays a modulator role in regular T cell functions and interleukin-10 production. Therefore, epidemiological and randomized studies are needed in the future to better understand the role of vitamin D in respiratory infections and asthma (8). In conclusion, our study showed that the decreased vitamin D levels in infants with bronchiolitis were associated with bronchiolitis severity.
