Abstract

Objective: In the recent years, oocyte donation programmes have widely spread worldwide becoming the drive of health tourism. In some countries the donation programmes are tightly regulated; whereas in some, the guidelines or regulations are not well defined. The aim of this study was to evaluate the donors’ awareness of the donation programmes and the ethical consequences in enrolling these programmes.

Material and Methods: A detailed questionnaire-based survey was conducted to evaluate the donors’ main drive to get involved in the donation programme and the donor’s knowledge and awareness of risk factors.

Results: Majority of the donors (70%) were undergoing donation programmes for financial gains through compensation. The donors were especially not aware of the long-term medical risks and the possibility of identity exposure through genetic screening.

Conclusion: The health professionals have the main duty to counsel the donors about the basic procedures and any possible problems they may face during the donation programmes. Reimbursement of oocyte donors is a slippery slope path in oocyte donation programmes. High compensation may make women to think that donation is a profession without considering possible risks. Furthermore, with the wider use of direct-to-consumer genetic testing, genetic anonymity may be at risk, thus the donors have to be counselled properly. Therefore, in this era of health tourism, it is crucial to set up well-defined counselling bodies in all oocyte donation centres and enable the donors to make an informed choice in becoming oocyte donors.

Keywords: Oocyte donation, donor programme, donors, ethics

Introduction

Third party reproduction has become one of the widely used fertility treatments that involve use of gametes or embryos. With the improvements in oocyte cryopreservation techniques, a new era of health tourism has been initiated. The first oocyte donation was performed in 1983 in Austria and since then it has become a part of the routine assisted reproductive technology (ART) treatments [1]. Thousands of oocyte donations have been applied throughout the world resulting in thousands of births [2]. The main drive of oocyte donations is the inability of females to get pregnant using their own gametes due to poor oocyte quality after several failed in vitro fertilization (IVF) attempts or low/absent ovarian reserve because of advanced maternal age or premature ovarian failure. Oocyte donation can also be offered to woman with a heritable genetic disease to prevent the transmission of the disorder to the next generation, though preimplantation genetic diagnosis is usually preferred with no history of infertility. Least commonly, oocyte donations can be offered to same-sex male couples in adjunct to surrogacy.

Reproductive cells, especially oocyte cells, are supplied by a limited number of donors, resembling to other organ and tissue donations. Controlled ovarian hyperstimulation (COH) protocols have to be applied to all patients undergoing ART treatments. These protocols have been long revised and although more studies are being performed to enhance them, they are very standardised. However, there is always a worry that higher doses of drugs may be used to obtain more oocytes from the donors since the number of patients seeking donor oocytes is always higher than the number of donors. The short- and long-term medical risks of COH have been investigated with a limited number of studies. These studies have suggested that there is an increased risk of
early menopause and ovarian cancers [3]. Furthermore, donors may undergo multiple COH cycles, especially in countries where there are no regulations.

Oocyte donation process is considered to be a slippery slope process since it does not benefit the donor directly [4]–[7]. The majority of the oocyte banks provide financial compensation that raises substantial ethical concerns on the quality of informed consent [8] with the exploitation of the oocyte donors [9]–[11]. There has been always a big concern on the undue inducement that affects the judgement of the women’s ability to rationalise and evaluate the burdens and risks of participating in the oocyte donation programme [12]. There have been long term discussions where females with low socio-economic status are exploited by donation programmes [13]. One of the other concerning areas in the donation programmes is the sufficiency of counselling provided to the donors.

In addition to these objective and subjective matters of oocyte donations, concerns of elimination of anonymity have arisen due to the direct to consumer (DTC) genetic testing. Throughout the world, oocyte banks have been established with stored donor oocytes of mostly anonymous donations [2]. In the recent years, more and more people are taking the DTC genetic testing without even consulting with a clinician. Mostly, individuals are taking these tests to uncover their ancestry or to learn about their possible health issues [14]. However, a number of cases have been reported where the child is seeking the biological parent using the results of DTC genetic testing [1], [15]. Furthermore, we are entering into the era of personalised medicine, where genomic databases storing patients’ information are being formed to provide a better individualised medical care. A person’s genome can be sequenced even before they are born. It is still not exactly clear to whom this data will be available and under what circumstances. However, it is highly unrealistic to expect genomic anonymity in this genomic era.

Although in some countries the donation programmes are tightly regulated; in some, there are no strict guidelines or regulations [1]. This introduces many issues in such countries where the oocyte donations become the drive of health tourism. A scarce number of studies have investigated this, however many factors, such as the demographics, education level and socio-economic status, may alter the reasons of the involvement in the oocyte donation programmes. The aim of this study was to evaluate the ethical aspects of oocyte donations, the counselling services provided to the donors and donors’ awareness of the consequences in undergoing donation programmes. More specifically; we intended to determine the counselling quality before the treatment, and the depth of the information provided by the health specialists. We aimed to investigate how well the donors’ perception was on the fate of the donated oocytes, the short- and long-term medical risks, and the ethical implications of the donation. Furthermore, we investigated the reasons of the donors to get involved in the oocyte donation programmes.

METHODS:
Ethical Approval
A total of 50 donors volunteered for this study. Ethical approval was granted by the Near East University Ethical Committee (Project number: YDU/2018/58-604) prior to commencement of the study and an informed consent was obtained from all the participants. Questionnaire based survey was used as an evaluation method. A thorough literature review was performed to prepare the questionnaire through the Likert scale (Appendix 1).

The questions were mainly focused on the evaluation of the reasons of the involvement in the donation programme, donor’s awareness and knowledge of risk factors and genetic screening.

Study population
The participation was anonymous and voluntary. The women included in this study were recruited as oocyte donors in a private IVF clinic as part of a donation programme. They had to meet specific requirements to become a donor and these requirements also determined their suitability to be included in this study. Donors had to be between 18 and 32 years of age and they had to be screened negative for sexually transmitted infections including human immunodeficiency virus, cytomegalovirus, hepatitis B and C. They should have normal physical and gynaecological examination and no familial history of congenital malformations or hereditary diseases. A good physical and mental health were also required to be an eligible donor. The potential donors meeting these requirements were assessed by the gynaecologist and counselled by the same gynaecologist and/or IVF nurse.

Subjective and Objective Questionnaires
The questionnaire was presented to the participants after they had been through the oocyte collection procedure and were fully recovered from anaesthesia. The survey was performed by an experienced nurse and/or an experienced embryologist. The demographic characteristics were reported for all the donors. These included age, level of education, marital status, reasons of involvement in the donation programme and socio-economic status. Subjective questionnaires were designed to interrogate the perceived understanding of the oocyte donations. These involved questions to rate how well the donors understood the oocyte donation process. The objective questionnaires involved interrogating the objective understanding, including the understanding of matters, such as “There is a risk that I can become pregnant naturally if I engage in sexual relationship during the donation process” or “I can change my mind about donating my oocytes”. Open-ended questions were also
recorded to specify the motivation of the involvement in the donation programme and to identify what had driven them to donate their oocytes. The answers were mainly grouped as, financial gain, helping couples who cannot get pregnant using the female partner’s oocytes and other reasons, such as knowing the person who needed the oocytes.

**Statistical Analysis**

Fisher’s exact test was performed and the two-tailed *P* value of less than 0.05 was considered to be statistically significant.

**RESULTS**

In this study, a total of 50 donors volunteered to perform the survey investigating the main drive in the involvement of the oocyte donation programmes and the awareness of the procedure and the risks. Our cohort of oocyte donors indicated that the main reason of donating their oocytes was due to financial reasons. Seventy percent (*n*=35) of the donors underwent this programme to benefit from financial gains, 22% (*n*=11) stated that they have always wanted to help someone going through infertility problems and were donating mainly for altruistic reasons. The remaining 8% (*n*=4) donated oocytes for other reasons or did not want to disclose their particular reason (Figure 1).

These donors were further questioned regarding the number donation programmes they were involved in. Majority of the donors (80%, *n*=40) have donated their oocytes for multiple times. Overall, 12.5% (*n*=5) did not want to reveal the number of donations they previously have been through. Sixty eight percent (*n*=38) of the donors had undergone an average of 4.76 previous oocyte donations ranging from 2 to 9 COH cycles. Twenty one percent (*n*=7) of the donors further specified that they had donated oocytes in different ART centres.

The final part of this study investigated the knowledge of donors on: i) procedure before initiation of donation, ii) procedure during/after donation, iii) fate of oocytes after the donation, iv) short-term medical risks of the donation, v) long-term medical risks of the donation, and vi) ethical implications of the donation, such as the possibility of the identity disclosure through genetic testing. Overall, only 38% (*n*=19) donors were fully aware of all the procedures, fate of the oocytes and the medical risks. Of these well-informed donors, only 4% (*n*=2) were first-time donors (Figure 2). More than half of the donors with previous experience in donations (57.5%, *n*=23) were not fully aware of what the procedures were. The average rate of knowledge among donors with previous donation history was 88% (*n*=35), where the average rate of knowledge of first-time donors was 71% (*n*=7). The least informed donor was a first-time donor with a knowledge rate of 29%. Donors were relatively informed about the fate of the oocytes before and during the donation procedure. Overall, the donors were least informed on the long-term medical risks, in which 52% (*n*=20) stated that they were not informed about these risks at all. Furthermore, they were not well informed about the short-term medical risks such as risks associated with anaesthesia, infection/bleeding after oocyte collection and bruising from injections/withdrawal of blood. Twenty four percent (*n*=12) of the donors also stated that they were not informed about the possibility of identification after genetic testing. All the donors were aware of the risk of ovarian hyperstimulation syndrome (OHSS), however only four percent were aware of the risk of pregnancy during treatment cycle in case of unprotected sexual intercourse.

To investigate the knowledge of the donors with previous donations, 2x2 contingency tables were formed. The association between previous donation and the awareness was statistically significant (*P*<0.0001) for the first four categories; (i) procedure before initiation of donation, (ii) procedure during/after donation, (iii) fate of oocytes after the donation, (iv) short-term medical risks of the donation. The association between previous donation and awareness of the possibility of the identity disclosure through genetic testing was also statistically significant (*P*<0.05). However, donors with a previous donation history were equally as unaware as first-time donors about the long-term medical risks of donation (*P*>0.05, Figure 3).

**DISCUSSION**

Ethical and psychological aspects of oocyte donation programmes present distinct challenges in reproductive medicine. Donating oocytes are risky not only in terms of the actual medical procedure of obtaining oocytes but also in terms of the short- and long-term health risks that the procedure and the use of (repeated) supraphysiological hormones might have on the donors. Moreover, donors are often faced with the ethical dilemma of how their reproductive cells might be used and will usually have no hereditary autonomy after the donation procedure. Depending on the demographics of women participating in donation programmes, the reasons of becoming a donor show variability. Although some donors volunteer to become a donor with no reimbursement, some receive different amounts of compensation introducing issues on donor exploitation. The aim of this study was to investigate the drive of becoming oocyte donors and to assess how well these donors are informed about the stages of the procedure and the risks associated with it.

One of the most important aspects of donation programmes is sufficient counselling. The results of this study showed that the counselling on the most basic procedure, possible short- and long-term medical risks were not reasonable in North Cyprus. This finding is particularly worrying since it implies that the oocyte donors do not give a true informed consent. This was in agreement with previously published studies, in such only 34% of the donors were aware of COH procedure, only 20% were aware of the risk of bleeding or infection and only 15%
of ovarian torsion or damage [14]. Therefore, it is crucial to develop counselling services to improve the subjective and objective understanding for the oocyte donors. Although, counselling methods show variations in different ART clinics, they have the responsibility to ensure that the donors are well informed about the procedures and the risks. One-on-one discussion was suggested to be the only intervention to improve donor perception on the subject [16]. Therefore, it is a possibility that the clinics may adapt their counselling programme with a one-on-one discussion. Another important part of counselling is to cover the concept of anonymity. Both the parents using the donated oocytes and the donors have to be fully informed that the DNA obtained from the children reveals the information on the biological parents. The anonymity in the genomic era where DTC genetic testing is becoming more and more available will be eliminated rapidly. The challenges faced due to compensations combined with limited information given might make donating oocytes seem a risk-free, comfortable way of earning money.

One of the biggest societal and ethical concerns of oocyte donations is the amount of reimbursement to avoid exploitation of the donors. In most countries, there are strict criteria, governmental laws and regulations to perform any kind of reproductive donation. A recent study conducted in Netherlands reported that a typical donor is a very well-educated, feminine, and a fellow who has agreed to make donations for altruistic reasons [13]. None of the women who participated in the study reported that the earnings from the financial direction motivated them and did not show them as the reasons for the donation [13]. Another multi-centre study reported that majority of the donors undergo the donation programme for altruistic reasons, however the socio-demographics and motivation of donors vary hugely depending on the country of donation [9]. On the contrary, financial motivation, especially as the compensation increases, has been reported to be the main drive of oocyte donors in the USA [9]. Similarly, in this study 70% of the participants clearly stated that financial gains were their main reason of going through the donation programme. One of the main reasons of the inconsistency of these motivations may be due to the differences in the socio-economic status of the local donors in North Cyprus compared to other European countries where similar studies were conducted. This introduces critical ethical and psychological issues in countries like North Cyprus which is considered to be a third world country. The biggest difficulties in such countries are the lack of robust, local, governmental regulations and/or enforcement of existing regulations on the ART centres carrying out oocyte donation procedures. Therefore, especially not having a set limit on the reimbursement makes it a very tempting encouragement for the potential donors. On the other hand, even though the reimbursement is controversial, it has been proposed that it is not realistic for women to go through the donation programme just based on altruistic basis [9], [17]. Even women with altruistic motivation, inconveniences; such as transport to the ART clinic and taking time off from work; should have a small financial compensation to encourage them to go through the donation process [9].

Previously published studies reported that these donors with altruistic motivation are usually married and well-educated [17]–[20]; whereas donors who go through the donation programme due to financial gains have variable demographics and tend to be single and younger [21]–[23]. The mean age of oocyte donors in this study is lower than reported in other studies [19], [23]–[25] and they are mostly single students. Therefore, the demographics of the donors in North Cyprus are different compared to the other parts of Europe. Due to the differences of laws and regulations in each country, the results of these kinds of studies vary significantly [26]. Throughout Europe and USA, the legislation on anonymity or the reimbursement vary reflecting the different drives of involvement in the oocyte donation programmes. There is a need of more studies to investigate the motivation and the counselling in different countries to obtain a better insight to avoid donor exploitation. Our results showed that the donors were being informed selectively about certain risks and they gained knowledge with multiple donation cycles by experience. All donors were informed about the OHSS as this is a very serious and life-threatening condition. However, less number of donors knew about the risk of (multiple/ectopic) pregnancy following unprotected sexual intercourse during the treatment cycle. Both of these are very serious conditions with short-term effects and the clinic would be in huge distress in the case they happen. However, information provided about long-term medical risks, which might frighten the potential donors, were not provided sufficiently. Even though donors with previous donation history were generally more informed, they were equally as uninformed as a first-time donor about the possible long-term consequences of the donation. Therefore, a standardised counselling protocol is largely missing. Furthermore, there is a critical risk of donor exploitation, especially in third world countries where the donors tend to have lower socio-economic status and lower self-esteem. Therefore, it is advised to set up large-scale longitudinal studies to establish sufficient counselling services and set an amount for compensation for each country without the risk of donor exploitation.

**Questionnaire for Oocyte Donors Appendix**
1. Why would you like to be an egg donor?
   a. I think it would be a rewarding experience for me.
   b. I always wanted to help someone with infertility difficulties.
   c. I think the process is exciting.
   d. I need the money.
   e. Other
2. Is this your first time as a donor?
   a. Yes
   b. No
   If no, how many donation cycles were you involved in?

Was it in a different clinic?

3. Were you informed that you will be treated with fertility drugs to assist ovulation?
   a. Yes
   b. No
4. Were you informed that you will be monitored with ultrasound equipment?
   a. Yes
   b. No
5. Were you informed that you will have eggs removed surgically either by laparoscopic or ultrasound direct follicle aspiration?
   a. Yes
   b. No
6. Were you informed that the assisted reproductive technology medical staff will attempt to fertilize some or all of the donated eggs with sperm collected from the Husband or with donated sperm?
   a. Yes
   b. No
7. Were you informed that the embryos produced will be transferred to the uterus of the female recipient?
   a. Yes
   b. No
8. Were you informed that you relinquish all claims to the eggs and any child that results from the use of eggs donated and from the moment of retrieval of the eggs, the eggs belong to the recipient and that the recipient have the sole and exclusive right to determine any medical procedures and treatment regarding the eggs?
   a. Yes
   b. No
9. Were you informed that physical examination will be conducted, including taking blood and other body fluids, as well as a test for exposure to the HIV (AIDS) virus, drug screening, genetic testing and psychological screening for the purpose of giving the assisted reproductive technology medical staff sufficient information to determine whether you are an acceptable egg donor?
   a. Yes
   b. No
10. Your personal information is definitely not shared with the patients. Were you informed that there is a possibility that a genetic test may identify you as the biological mother of any children born as a result of donation?
    a. Yes
    b. No
11. Were you informed the risks of egg donations that may include:
    11. Overstimulation of ovaries, which could result in a feeling of bloating or abdominal discomfort.
        a. Yes
        b. No
    12. Risks associated with general anesthesia if used in connection with egg retrieval.
        a. Yes
        b. No
    13. Discomfort, infection and bleeding from laparoscopic or vaginal ultrasound recovery of eggs.
        a. Yes
        b. No
    14. Pregnancy or multiple pregnancies resulting from having vaginal intercourse during the cycle if adequate contraception is not used.
15. Bruising from injections and withdrawal of blood.
   a. Yes
   b. No

16. There may be certain long-term risks associated with the use of fertility drugs. These risks include ovarian cyst formation or rupture, ovarian over-stimulation, possible increased risk for ovarian cancer.
   a. Yes
   b. No
