Introduction

Pseudohypoparathyroidism (PHP) is an autosomal dominant disorder, which is related with parathormone target organ resistance resulting from mutations in guanine nucleotide binding protein (G protein) and alpha stimulating activity polypeptide 1 (GNAS1) genes. It is characterized by hypocalcemia, hyperphosphatemia and high blood parathormone (PTH). Typical phenotypic symptoms and additional hormonal resistance can be observed in type Ia, which is also known as Albright hereditary osteodystrophy. Our patient was an eight-year and nine-month old girl with typical Albright’s hereditary osteodystrophy phenotype including short stature, obesity, round face, low nasal bridge, shortened metacarpals, and mild mental retardation. In her biochemical examination, high PTH level and hypothyroidism is detected in spite of normal calcium and phosphor levels. As a result of clinic and laboratory tests, the findings were consistent with PHP type Ia with normocalcemia. In her guanine nucleotide binding protein (G protein), alpha stimulating activity polypeptide 1 (GNAS1) gene serial analysis, C-308T>C (p1103T) transformation was detected, which was previously reported in a PHP type Ia patient. In this report, we’ve aimed to emphasize the fact that calcium and phosphor level in the blood of the patient with PHP type Ia can be measured normal.

Case Report

Eight-year and nine-month-old female patient was admitted to the hospital with the complaint of having short stature with a height of 117.2 cm (<3p, -2.5 SDS) and weight of 28.9 kg (50-75p, 0.124 SDS). She was term born, birth weight was 3100 gr (25-50 p) and birth height was 50 cm (50-75 p), respectively. Her parents were

third-degree relatives. Her father’s and mother’s heights were 165 cm (-1.65 SDS), and 135.9 cm (-4.2 SDS), respectively. She had healthy four siblings. Her physical examination at presentation showed a short stature, obesity, round face, low nasal bridge, and shortened metacarpals (picture 1 and 2). Her pubertal stage was in tanner phase 1. She was evaluated as mentally retarded in a mild degree.

Skeletal maturation assessment by direct hand wrist radiography revealed shortened metacarpals and metatarsals (picture 3) and her bone age was consistent with her age. Her thyroid ultrasonography and cranial magnetic resonance imaging were both reported as normal. Hypothyroidism and elevated PTH levels with normocalcemia and normal 25-OH vitamin D levels were detected in her laboratory tests. Laboratory findings including complete blood counts, biochemical parameters, TSH, free T4, calcium, phosphorus, alkaline phosphatase, PTH level, 25-hydroxyvitamin D, insulin like growth factor 1 (IGF-1) were given in Table 1.

As a result of clinic and laboratory tests, the findings were consistent with PHP type Ia with hypothyroidism and normocalcemia, her GNAS gene sequencing analysis was performed; C-308T>C (p1103T) transformation was detected, which was previously reported in PHP type Ia patient. Oral L-thyroxine treatment was initiated to the patient. Her growth velocity and calcium and phosphorus levels are still on follow-up.

Written informed consent was obtained from the patient’s parents for publication of this case report.

Discussion

Pseudohypoparathyroidism Ia is the most prevalent PHP type. Along with typical phenotypic findings, cases showing heterogeneity have also been reported (12-14). Our patient had typical AHO phenotypes.

Transport system which is sensitive to parathormone consists of three sections namely receptor, adenyl cyclase and protein G. The GNAS gene encodes the alpha-stimulatory subunit (Gs) of the intracellular G protein, which stimulates the production of cAMP under certain physiologic conditions (7). Gs alpha protein activity in PHP-Ia is low as a result of GNAS I gene mutation therefore, sufficient c-Amp response to PTH cannot occur in receptor level (15-18). Resistance to other hormones which uses protein G as a second messenger, may also be observed. Moreover, the most common resistance is observed against TSH, which affects more than 90% of PHP patients type Ia (19,20). Previous reports have shown hypothyroidism may be the first manifestation of PHP type Ia in absence of hypocalcemia and elevated PTH levels (8-21). In our case, hypothyroidism with elevated TSH and decreased sT4 levels was detected.

The characteristic findings of the disorder are hypocalcemia, hyperphosphatemia and high level of PTH. However, previously normocalcemic cases have also been reported (10,22-24). Tamada et al. (24) reported a case with R358H mutation with normocalcemia. We have detected C-308T >C (p1103T) change in our case. The mechanism behind the fact of normocalcemia cannot be explained completely. It is proposed that normal serum calcium concentrations in these patients may be explained by the presence of normal bone responsiveness to PTH (10,25,26).

Further studies are needed on this issue.

In conclusion, we have presented a PHP type Ia patient with normocalcemia and hypothyroidism caused by C-308T >C (p1103T) change in the GNAS gene. In children with hypothyroidism without apparent etiology, GNAS1 gene mutations should be also considered even calcium levels are normal.
