Difficult Tracheotomy in Advanced Anaplastic Thyroid Carcinoma

Sedat Aydın, Mustafa Paksoy, Elif Uysal
İstanbul Kartal Dr. Lütfi Kırdar Training and Research Hospital, Clinic of Otolaryngology, İstanbul, Turkey

Introduction
Anaplastic thyroid carcinoma (ATC) is a rare and rapidly progressive malignancy of the thyroid gland with a poor prognosis. The cause of death in these patients is mostly due to invasion of the airway with mass and metastasis to the airway. The local destructive invasion of the mass and the compression of the trachea in a short time may lead to severe dyspnea and stridor in the patient. Tracheotomy is a palliative surgical approach that can be performed after endotracheal intubation in patients with severe respiratory distress. This patient with advanced ATC was admitted to the emergency department due to severe respiratory distress. After endotracheal intubation, the tracheotomy was performed with difficulty and the safety of respiratory tract was achieved. In such patients, respiratory airway management is presented with current literature review.

Case Report
A 49-year-old male patient was diagnosed with ATC after a biopsy in the health center he had applied to because of developed pain and swelling on his neck 6 months ago. He presented to the emergency department due to severe respiratory distress. After endotracheal intubation, the tracheotomy was performed with difficulty and the safety of respiratory tract was achieved. In such patients, respiratory airway management is presented with current literature review.

of our hospital because of the increasing swelling in his neck and severe respiratory distress and stridor presenting in a short time. In the examination of the patient who had no pathology in his medical history and family history, it was observed that he had difficult respiration and inspiratory stridor in the inspection. The mass was covering the whole neck and anatomic triangulation points could not be differentiated. It was stiff, fixed, about 15x20 cm and mostly lateralized to the right side of the neck. The flexible nasopharyngoscopy revealed bilateral cord vocal paralysis and increased secretion in the piriform sinuses. The opening between the two vocal folds was 2-3 mm. Previous neck and thorax computed tomography of the patient were reported as “15x17 cm mass lesion, involving both thyroid lobes and isthmus, having irregular margins and exhibiting heterogeneous enhancement, and margins cannot be clearly distinguished from the surrounding muscles and soft tissues, and sternocleidomastoid muscles” (Figures 1 and 2). Informed consent was obtained from the patient. The mass pushed the trachea to the right and was compressing the airway from the anterolateral side. An urgent tracheotomy was planned for breathing difficulty. However, because important triangulation points in the neck were lost, it was thought that tracheotomy would be safer after endotracheal intubation and endotracheal intubation was performed under general anesthesia. Then, a conventional Kocher incision was planned in case apron flap incision was required. During the subcutaneous flap elevation, which was difficult due to bleeding, stiff and hemorrhagic thyroid mass adherent to strap muscles and other surrounding tissues were encountered. The incision was extended to the apron flap incision as previously thought, in order to control the mass. It was seen that the mass deviated the trachea to the right, extending to the posterior end of the sternum. Thyroid cartilage of the larynx was detected as an anatomical triangulation point in the neck. It was aimed to reach tracheal rings by following this structure downwards. In the meantime, with the help of the “harmonic scalpel” vascular sealing device that provided technological innovation, the thyroid right lobe and the mass thought to be derived from this lobe were partially excised and the tracheal cartilages were reached. The trachea was entered from the place where the second ring was thought to be (Figure 3). The patient was sedated and was taken to the intensive care unit with intravenous antibiotic and fluid support. Because the patient had postoperative induration and discharge in his neck, antibiotic treatment was continued as ultrasound revealed suspected abscess. The patient died in the intensive care unit after 14 days due to sudden bradycardia and cardiac arrest.

Discussion

Treatment options of ATK include surgery, chemotherapy, radiotherapy and combined therapies. However, the assessment of patients' airway is of critical importance. The cause of death in patients with ATC is often distant metastases with airway involvement, bilateral vocal cord paralysis and respiratory problems. The tracheotomy or cricothyrotomy procedure provides palliative and transient airway solution. This issue should be discussed with the patient and his/her relatives and consent must be taken. The survival in patients who underwent tracheotomy was

![Figure 1. In coronal view of computed tomography scan of head and neck; a mass of 15x17 cm with irregular margins and heterogeneous contrast enhancement is observed, which invades both thyroid lobe and isthmus, and thus cannot be clearly distinguished from surrounding soft tissues](image1)

![Figure 2. In sagittal view of computed tomography scan of head and neck; it is observed that the same mass has filled the thyroid space and narrowed the tracheal lumen](image2)

![Figure 3. A view of tracheotomy after partially tumor excision of the istmus region, severe destructive mass in the trachea drastically eliminated the anatomical guiding points](image3)
found to be shorter than in patients who underwent “debulking” surgery (9). However, it is important to note that in patients with ATC, respiratory problems are likely to occur until the tracheotomy stage. Because of the presence of malignancy and radiotherapy in these patients, wound healing in the tracheotomy region is not fast and healthy. For this reason, the tumor tissue can continue to grow from the tracheotomy line or its surroundings, leading to bleeding (10). In our case, abscess formation was detected after tracheotomy.

The fact that the mass causes respiratory distress in patients with ATC means that the mass grows and closes the surgical access ways to the trachea in the midline of the neck. Another problem is the displacement of the trachea due to the compression effect of the mass during tracheotomy. ATA recommends that tracheotomy should be performed under operating conditions and under general anesthesia as we did in our case (3-11).

As the ATC is progressing rapidly, a large mass is often encountered in the neck midline when respiratory distress occurs in patients. Because of this mass, “debulking” surgery is required to reach the trachea. Displacement of the trachea, stiffness and blood supply of the mass should be considered during this surgery. At this stage, the importance of preoperative radiological evaluation of the patient is revealed. The shortest and easiest way of access to the trachea should be evaluated preoperatively and the size of the surgery should be determined preoperatively. During “debulking” surgery, electrocautery should be used to reduce both the duration of surgery and post-operative bleeding. Standard tracheotomy cannulae can be short in these patients because reaching the trachea with “debulking” surgery also increases the distance between the skin and the trachea. In this stage, length-adjustable cannulas or intubation tube can be used (9). It is important to fix the cannula or tube to prevent dislocation (12). In our case, since length-adjustable tracheotomy cannula was not available at the time, a 7.0 endotracheal intubation tube was used and it was fixed to the surrounding neck skin.

In addition, the light to be advanced through the trachea can be followed by fiberoptic endoscopy during tracheotomy to help locate the trachea, which is displaced by external pressure (9). In our case, trachea was revealed after “debulking” surgery and there was no need for fiberoptic endoscopy guidance.

In conclusion, after the laryngeal examination with flexible nasopharyngoscopy and tracheotomy is planned for maintaining airway safety in cases of ATC admitting to emergency departments with severe respiratory distress, one first should get ready for a problematic tracheotomy following endotracheal intubation in the operating room conditions, as in our case. We believe that tracheotomy would be safe by reaching tracheal cartilages guided by thyroid notch and thyroid cartilage with a large incision, in difficult tracheotomy cases where triangulation points disappear, as in our case.

**Informed Consent:** Informed consent was obtained from the patient.

**Peer-review:** Externally peer-reviewed.
