Abstract

Aortic valve stenosis is common in the elderly. Nowadays surgical aortic valve replacement has still been the gold standard of management, but many patients have been excluded from surgery given that they are very old, frail, or have comorbidities that increase operative risks. In the last decade, transcatheter aortic valve implantation (TAVI) has emerged as a new treatment option for these patients. Despite its being less invasive than surgery, TAVI has rare but fatal complications like vascular injuries. Vascular injuries are the most common complications after TAVI, and they range from dissection to perforation and acute thrombotic occlusion. We report a case of left main coronary artery occlusion following TAVI that caused cardiac arrest and was managed successfully with emergency percutaneous coronary intervention.

Keywords: Transcatheter aortic valve implantation (TAVI), percutaneous coronary intervention, left main occlusion

Introduction

Transcatheter aortic valve implantation (TAVI) is an alternative treatment to surgical aortic replacement in patients who have severe aortic stenosis and high surgical risk¹. Since its first description in 2002, it has been performed successfully in worldwide². But despite its being less invasive than surgery, TAVI has rare but fatal complications like coronary obstruction. We report here a case of left main coronary artery (LMCA)
occlusion following TAVI that caused cardiac arrest and was managed successfully with emergency percutaneous coronary intervention (PCI).

Case Report

An 83-year-old male patient presented to our clinic with decompensated heart failure. He had hypertension, diabetes, and chronic obstructive pulmonary disease. On the physical examination, we found common rales in both lungs. Echocardiogram showed severe aortic stenosis (Pg Max/Mean=110/60 mmHg) and normal LV ejection fraction, 2-3. degree mitral regurgitation, 3. degree aortic regurgitation, and 2. degree tricuspid regurgitation. His systolic pulmonary artery pressure was 55 mmHg. After the stabilization of the patient, the risk scores were calculated for aortic surgery (Log. Euroscore was 21%, Euroscore 2 was 14 %, STS score was 8,7 %) and the patient was accepted to have high surgical risk for surgery in our cardiology, cardiovascular surgery, and cardiac anesthesia joint committee. So, we decided to perform TAVI. The super-stiff wire was inserted into the left ventricle through the left Amplatz-2 catheter via left femoral artery. The delivery system was advanced and predilatation was performed by creating hypotension at the level of the aortic valve under high-speed pacemaker (Figure 1A).

Then, 29 mm Edwards Sapien XT aortic valve level was adjusted and the valve was implanted using balloon under high-speed pacemaker (Figure 1B, 1C). Valve placement was performed without any complications. No complication was detected in the patient’s aortography and the procedure was ended. While the femoral closure was going on, the patient’s hemodynamic impaired and then the patient had cardiac arrest and was immediately intubated. Echocardiography showed no pericardial effusion. At fluoroscopy, bioprosthetic valve was in place. Coronary angiography was performed from the contralateral groin. There was no flow from the proximal left main coronary artery (Figure 1D). Then, under the CPR, a 0,014-inch guidewire was advanced into LAD and multiple balloon angioplasty was performed with a 2.5x15 and 3.0x20 mm balloon (Figure 2A, 2B). A 3.5x25 mm Commander BMS was implanted from LMCA to LAD and TIMI 2 flow was provided both in LAD and CFX artery. Then, the patient’s rhythm was achieved. (Figure 2C, 2D). The patient was taken to the intensive care unit. He was arrested again after 5 hours and the rhythm could not be achieved despite the CPR for 45 minutes and the patient was exitus.

Discussion

TAVI includes the insertion of a prosthetic valve into the stenotic aortic valve through a vascular access without the need for open heart surgery. Despite its widespread use and increasing experience of surgeons, TAVI has life-threatening complications especially vascular injuries. Complication rates differ with the experience of surgeon, the size of the device, the site of catheter access, as well as the use of pre-procedural screening. The coronary obstruction was first reported in 2006 by Webbs. The frequency of this complication ranges from 0% to 4 % but the mean frequency has been reported as 1% in large studies(3-8). Clinical manifestation of this...
situation usually includes persistent hypotension, ST segment changes (elevation or depression), ventricular arrhythmias and sudden cardiac arrest immediately after valve implantation. The most known risk factors of this complication are shorter (<10 mm) distance between the left coronary ostium and aortic annulus, narrow aortic annulus, the presence of bulky calcium nodules on aortic leaflets, and use of balloon-expandable valve (6,9). Coronary ostium height cut off level of 10 mm or shorter increases the risk of coronary obstruction (10). Kapadia et al. (11) recommended that a 0.014 mm guidewire can be advanced into LAD through a guiding catheter during valve deployment so that we can quickly access and if necessary dilate the left main trunk. In cases of severe hypotension, ST segment changes (elevation or depression), ventricular arrhythmias and sudden cardiac arrest, LMCA occlusion is the major complication apart from rupture. In our institution, we routinely take CT angiography before the TAVI procedure. In our case the distance between left coronary ostium and aortic annulus was 8.02 mm (Figure 2E). In our patient, we believe that shorter left coronary ostium height and bulky calcific nodule on aortic leaflet caused left main coronary occlusion. In a retrograde review, we did not advance a guidewire into LAD but we treated the patient successfully with stenting and after stenting the rhythm was achieved.

Conclusion

As a result, in situations following TAVI, such as severe hypotension, ST segment changes (elevation or depression), ventricular arrhythmias, and sudden cardiac arrest emergency coronary angiography must be performed from the contralateral groin and LMCA occlusion must be

Figure 2. A. PTCA was performed with a 2.5x15 and 3.0x20 mm balloons. B. 3.5x25 mm Commander BMS was implanted from LMCA to LAD. C. After stent, TIMI 2 flow was provided both LAD and CFX. D. The distance between left coronary ostium and aortic annulus was 8.02 mm

Keskin et al. A Rare Complication After TAVI: Acute Left Main Coronary Artery Occlusion and Successful Percutaneous Treatment
treated with emergency angioplasty and stenting. In the TAVI procedure, a detailed preoperative evaluation is as important as the procedure.
