INTRODUCTION

Benign paroxysmal positional vertigo (BPPV) is the most common cause of peripheral vertigo in the general population (1). BPPV is characterized by vertigo that is triggered by head movements and lasts for seconds, and accompanied by a feeling of imbalance and nausea. In the pathophysiology of BPPV, there are two theories called cupulolithiasis and canalithiasis. There are three semicircular canals located perpendicular to each other in the inner ear and sensing the angular movements of the head: posterior, lateral (horizontal), superior (anterior) canal crura are associated with the utricle, known as autolytic organ. Calcium (Ca) carbonate crystals are found in the otoconial layer above the maculae found in the utricle. The otoconia separated from the utricle macula can pass into semicircular canals. Vertigo and nystagmus can occur when these otoconia stimulates cupula. The “canalithiasis” theory suggests that the free movement of these otoconia in the canal plays a role in the pathophysiology of the disease. It was first described by Hall, Ruby and McClure in 1979 and was first proven in vivo by Parnes and McClure in 1992. “Cupulolithiasis”, defined by Schuknecht in 1969, refers to the adherence of the otoconia to the cupula (2). Otoconia contains Ca carbonate in the form of Ca crystals and an organic core consisting mainly of glycoproteins. Ca metabolism also plays a primary role in the synthesis/absorption of otoconia and is therefore theoretically thought to be an etiological factor at the onset of BPPV (3). The aim of our study was to compare 25-hydroxy (25-OH) vitamin D levels in patients with idiopathic BPPV and healthy controls, and to investigate the role of 25-OH vitamin D in the development of BPPV.

METHODS

One hundred and twenty-five (100 female and 25 male, mean age=52±14 years) patients, who were admitted to the vertigo outpatient clinic between June 2018 and September 2018 and were diagnosed with idiopathic BPPV, were included in this retrospective case-control study. The control group was composed of 101 healthy subjects without vertigo. The control group was matched for age and sex. The diagnosis of idiopathic BPPV was made according to the criteria of the American Academy of Otolaryngology (4). Patients with Meniere’s disease, vestibular migraine, labyrinth hypofunction, head trauma or other vestibular diseases were excluded. The patients’ medical records were reviewed to assess the medical history and the results of the oto-rhino-laryngology examination. The control group consisted of healthy subjects without vertigo. The control group was matched for age and sex. 25-OH vitamin D levels were measured using a chemiluminescence immunoassay method (Siemens, USA) in our laboratory. The significance of differences between the 2 groups was calculated using the Student’s t-test. A p-value of <0.05 was considered statistically significant.
consisted of 101 (74 female and 27 male, mean age=48±13 years) healthy volunteers. The patients had no history of neurological symptoms or vestibular disease. Patients with neurotologic symptoms and complaints of dizziness and imbalance were excluded from the study. All participants did not receive Ca or vitamin D treatment within the last year.

Vestibular evaluation was performed using computerized (videonystagmography: ICS Charter EP, GN Otometrics, USA). BPPV was diagnosed by Dix-Hallpike and Pagnini-McClure maneuvers. There was posterior canal involvement in 80 patients (64%), horizontal canal involvement in 38 patients (30.4%) and anterior canal involvement in seven patients (5.6%). Epley maneuver was used in patients with posterior canal involvement and Barbecue maneuver was applied to those with horizontal canal involvement. In the anterior canal involvement, “reverse Epley maneuver” was performed. Canalithiasis was detected in 72% (90 patients) of these patients and cupulolithiasis was responsible for the pathophysiology in 28% (35 patients) (Table 1). Blood was collected from patients with BBPV and healthy volunteers and 25-OH vitamin D levels were measured. 25-OH vitamin D levels were classified as normal (≥30 ng/mL), insufficient (>20 to <30 ng/mL) and deficiency (≤20 ng/mL). The approval of the Ethics Committee was obtained (dated: 6.11.2018, numbered: 48670771-514.10). Informed consent was obtained from the patients.

**Statistical Analysis**

Statistical analysis was performed using SPSS version 23.0. Descriptive data are presented using mean and standard deviation for normally distributed variables, and median, minimum and maximum values for non-normally distributed variables (and frequency tables for ordinal variables). Chi-square was used to compare categorical variables. The suitability of the measured variables to normal distribution was examined by visual (histogram) and analytical methods (Kolmogorov-Smirnov/Shapiro-Wilk tests). Pairwise comparisons were performed using Student’s t-test for normally distributed parameters and Mann-Whitney U and Kruskal-Wallis tests for non-normally distributed parameters. P<0.05 was evaluated as statistically significant.

**Results**

The mean serum 25-OH vitamin D levels were 16.36 ng/mL (3.52-53.91) in the BBPV group and 17.09 ng/mL (4.46-53.51) in the control group. Vitamin D levels were low in both groups. In the BBPV group, 81 patients (65.3%) had serum 25-OH vitamin D deficiency, 33 patients (26.6%) had insufficient and 10 patients (8.1%) had normal levels. In the control group, 74 patients (73.3%) had serum 25-OH vitamin D deficiency, 16 patients (15.8%) had insufficient and 11 patients (10.9%) had normal levels (Table 2). There was no statistically significant difference between the BBPV

group and control group in terms of 25-OH vitamin D deficiency (p=0.139). There was no difference between 25-OH vitamin D levels in BPPV patients regarding affected canals (p=0.724).

**DISCUSSION**

BPPV is the most common cause of peripheral vertigo at any age. The mechanism of BPPV is explained by the passage of the otocoria separated from the utricle into semicircular canals. There is no consensus on the factors that cause BPPV. Since the etiologic factors are unclear, most cases are considered idiopathic. Predisposing factors are senility, female gender, hormonal factors and viral causes (4). Inner ear consists of cochlea and labyrinth system. The bony labyrinth consists of three semicircular canals: superior (anterior), posterior and horizontal (lateral). There is a fluid called perilymph in the bony labyrinth. Membranous labyrinth consists of utricle, saccule and membranous semicircular canals, and it contains endolymph. Membranous semicircular canals are located perpendicular to each other. The dilated parts are called ampulla. There are special cells in this region called “crista ampullaris” that is the sensory organ of balance. Within the wall of the utricle, there are cells called the macula of utricle, which lie horizontally and receive the sense of balance, and supporting cells. These cells have Ca^{2+} particles called otoconia. Otoconia crystals have central and peripheral portions. The core is predominantly organic with a lower Ca^{2+} level and the periphery is largely inorganic with a higher Ca^{2+} level (5). Endolymphatic Ca^{2+} concentration is critical for normal auditory and balance system (6-8). According to theoretical considerations, a link between otolytic disorders and vitamin D deficiency is highly probable. Endolymphatic (cochlea 23 μM and vestibule 280 μM) Ca concentration is much lower than perilymph. Yamauchi et al. (9) first demonstrated the expression of a complete Ca^{2+} absorptive system in cochlear and vestibular tissues in mice. Regulation by vitamin D allows this system to be regulated at the transcript level. Brookes (8) thinks that low endolymphatic Ca^{2+} concentrations at pathological level are the cause of hearing loss due to vitamin D deficiency and hypoparathyroidism. Karataş et al. (3) conducted a study in our country and compared the prevalence of osteoporosis and vitamin D deficiency in 78 BPPV patients and in 78 controls. Osteoporosis and vitamin D deficiency rates in BPPV patients were very high. The mean serum 25-OH vitamin D levels in BPPV patients and controls were 23.0±14.4 ng/mL and 17.0±12.3 ng/mL respectively. The prevalence of vitamin D deficiency in these two groups was 28% (22 individuals) and 40% (31 individuals), respectively. However, there was no significant difference in the prevalence of osteoporosis and vitamin D deficiency between BPPV group and controls. Since the prevalence of osteoporosis and vitamin D deficiency is quite high in the general population, they thought that osteoporosis and vitamin D deficiency are not risk factors for BPPV. In our study, mean serum 25-OH vitamin D levels were 16.36 ng/mL (3.52-53.91) in the BPPV group and 17.09 ng/mL (4.46-53.51) in the control group. Vitamin D levels were low in both groups. There was no statistical difference between the groups. Lee et al. (4) evaluated the relationship between Ca^{2+} and vitamin D status, and the presence of BPPV formation and bone biochemical markers in 132 osteoporotic patients diagnosed with idiopathic BPPV. They divided patients into three groups according to bone mineral density (BMD). The incidence of vitamin D deficiency was 11.8% (4/34) in the normal BMD group, 15% (6/40) in the osteopenia group, and 43.1% (25/58) in the osteoporosis group. They found a positive correlation between 25-OH vitamin D and BMD results in BPPV patients. They reported that the prevalence of BPPV in osteoporotic patients is associated with vitamin D deficiency and systemically high bone turnover rates, and may impair local Ca^{2+} homeostasis in the inner ear. Han et al. (10) examined the BMD and serum 25-OH vitamin D levels of 80 postmenopausal women with BPPV and compared them with healthy volunteers. Decreased BMD was significantly higher in women with BPPV than in healthy controls (71.8% vs. 51.2%). Mean serum 25-OH vitamin D levels were also significantly lower in women with BPPV than in healthy controls (19.1±5.2 vs. 22.5±5.8, p<0.001). They thought that low 25-OH vitamin D might be a risk factor for BPPV in the postmenopausal period. Maslovara et al. (11) compared serum vitamin D vitamin levels in BPPV patients with and without recurrence, and found no significant difference. Most of the patients found low serum vitamin D level and recommended vitamin D for these patients. Vitamin D levels were significantly lower in patients with clinical canalithiasis than cupulolithiasis. In our study, 72% of cases had canalithiasis pathology and 28% had cupulolithiasis. There was no difference in vitamin D deficiency.

Talaat et al. (12) divided 80 patients (52 females, 28 males, mean age=47.6±9.1 years, range=31-71 years) with BPPV into two groups: 36 patients with primary and 44 patients with recurrent BPPV. The control group included 100 healthy volunteers with similar age and gender distribution. BMD and serum 25-OH vitamin D were measured. Vitamin D levels were significantly lower in the recurrence group (p<0.05). Studies that correlate BPPV and both vitamin D deficiency and low BMD suggest that these disorders should be investigated and treated in patients with recurrence. Büki et al. (13) measured 25-OH vitamin D levels in 18 BPPV patients and found it to be low. Four of these patients were recurrent cases with 4-6 attacks per year. Patients with idiopathic
positional vertigo had a low mean serum 25-OH vitamin D (23 ng/mL) levels similar to that of the general Austrian population at high rates. Patients with recurrences were given vitamin D and their serum levels were corrected. They were followed-up for 8 months and vertigo attacks did not recur after vitamin D supplementation. They suggest further epidemiological research to determine whether BPPV patients with low vitamin D levels may benefit from supplementation and the effect of correcting vitamin D deficiency on vertigo recurrence. Jeong et al. (14) measured 25-OH vitamin D serum levels in 100 patients (63 female and 37 male, mean age=61.8±11.6 years) with idiopathic BPPV and compared the data with 192 controls (101 female and 91 male, mean age=60.3±11.3 years). Serum 25-OH vitamin D level was lower in BPPV patients (14.4±8.4 vs. 19.1±6.8 ng/mL, p=0.001). Moreover, patients with BPPV showed a higher prevalence of lower serum 25-OH vitamin D (≤20 ng/mL, 80.0 vs. 60.1%, p<0.001) than controls. It was shown that there was a relationship between idiopathic BPPV and decreased serum 25-OH vitamin D. Decreased serum 25-OH vitamin D may be a risk factor for BPPV.

**CONCLUSION**
The relationship between idiopathic BPPV and vitamin D deficiency is controversial in the literature. As in our country, vitamin D deficiency is common in populations with short and variable sun exposure. We found low levels of vitamin D in both study and control groups. In this respect, further studies are needed to investigate the relationship between BPPV and vitamin D deficiency.

**Ethics**

**Ethics Committee Approval:** Ethics committee approval was received for this study from the local Ethics Committee of Okmeydani Training and Research Hospital (dated: 6.11.2018, numbered: 48670771-514.10).

**Informed Consent:** Informed consent was obtained from the patients.

**Peer-review:** Externally peer-reviewed.

**Authorship Contributions**

**Conflict of Interest:** The authors declare no conflict of interest.
