MicroRNA in Patients with Hepatitis B and Hepatitis C Virus Associated Hepatocellular Carcinoma and Cirrhosis

Hepatit B ve Hepatit C İlişkili Hepatosellüler Karsinom ve Siroz Olgularında microRNA

ABSTRACT

Objectives: The aim of this study was to determine the potentials of hsa-microRNAs (miRNA)-21-3p, hsa-miRNA-29a-3p, hsa-miRNA-122-3p, hsa-miRNA-192-5p in Hepatitis B (HBV) and HCV related hepatocellular carcinoma (HCC) and liver cirrhosis (LC) cases, being biomarkers by examining their levels.

Materials and Methods: Sixty patients and 26 healthy volunteers were included in the study. Total RNA isolation in the serum samples was performed with the Direct-zol™ RNA MiniPrep (Zymo Research Corp., USA) commercial kit followed by cDNA synthesis and real-time polymerase chain reaction amplification with EPIK miRNA Select Hi/Lo-ROX (Bioline Reagents Ltd., USA). For amplification and analysis, Rotor-Gene Q (QIAGEN, Germany) instrument was used and statistical analyses were performed with SPSS 21 (IBM, USA) program.

Results: Hsa-miRNA-21-3p and hsa-miRNA-122-3p levels increased 3-4 fold in patients without HCV related LC (HCV-LC) and hsa-miRNA-29a-3p expression in HCV infected patients has significantly decreased (p<0.05). hsa-miRNA-192-5p showed a 3-fold increase in HBV related LC (HBV-LC) group (p<0.05) but not in other groups. The hsa-miRNA-122-3p value is increased in HCV-LC patients.

Conclusion: In our study, miRNA-21-3p and hsa-miRNA-122 for HBV-HCC and HCV-HCC diseases; hsa-miRNA-21-3p, hsa-miRNA-122 and hsa-miRNA-192-5p for HBV-LC; miRNA-29a-3p test for HCV-LC could be used as diagnostic markers.

Keywords: miRNA, hepatitis, hepatocellular carcinoma and cirrhosis

ÖZ

Amaç: Bu çalışmada hsa-mikroRNA (miRNA)-21-3p, hsa-miRNA-29a-3p, hsa-miRNA-122-3p, hsa-miRNA-192-5p’nin Hepatit B (HBV) ve HCV ilişkilii hepatosellüler karsinom (HCC) ve karaciğer sızrozu (KS) olgularındaki düzeyleri incelenerek, biyobelirteç olma potansiyellerinin belirlenmesi amaçlanmıştır.

Gereç ve Yöntemler: Çalışmaya 60 hasta ve 26 sağlıklı gönüllü dahil edilmiştir. Serum örneklerinde total RNA izolasyonu, Direct-zol™ RNA MiniPrep (Zymo Research Corp., USA) ticari kiti ile yapıldıktan sonra cDNA sentezi ve gerçek zamanlı polymeraz zincir reaksiyonu amplifikasyonu EPIK miRNA Select Hi/LO-ROX (Bioline Reagents Ltd., USA) ile gerçekleştirilmiştir. Amplifikasyon ve analizler için Rotor-Gene Q (QIAGEN, Germany) cihazı kullanılmış, istatistiksel analizler SPSS 21 (IBM, USA) programı ile yapılmıştır.

Bulgular: Hsa-miRNA-21-3p ve hsa-miRNA-122-3p seviyeleri HCV ilişkilii KS dışındaki hasta gruplarında 3-4 kat oranında artış göstermiş, HCV enfeksiyonu hastalarda hsa-miRNA-29a-3p ekspresyonunun azalmaları saptanmıştır (p<0.05). hsa-miRNA-192-5p ise HBV ilişkilii KS grubunda 3 kat artış gösterilen (p<0.05) diğer gruplarda belirgin farkliliklar göstermemiştir. hsa-miRNA-122-3p değerleri, HCV-KS hastalarında artmıştır.

Sonuç: Çalışmamızda, tanı belirteçleri olarak; HBV ilişkilii HCC ve HBV ilişkilii KS için miRNA-21-3p ve hsa-miRNA-122 testlerinin kullanılabileceğini belirlemiştir.

Anahtar Kelimeler: miRNA, hepatit, hepatosellüler karsinom ve siroz
Introduction

Hepatitis B virus (HBV) and HCV viruses are etiologic factors that cause liver damage. It is estimated that approximately 5 percent of the world's population has chronic HBV infection (approximately 350 million people). The prevalence of global HCV is approximately 2% and 180 million people are persistent HCV carriers. However, HBV/HCV infection rates vary from country to country. A significant percentage of chronic HBV and HCV carriers develop necroinflammatory liver diseases of different severity and course patterns such as persistent injury, cirrhosis, hepatic insufficiency and hepatocellular carcinoma (HCC) (1).

High morbidity and mortality rates of HCC require more specific methods and more effective strategies for diagnosis and treatment. Laboratory tests and imaging techniques such as ultrasonography along with histopathology, computed tomography and magnetic resonance are often used to diagnose it (2). All these diagnostic tools are limited due to their cost, availability and reproducibility (3). Therefore, some serum or tissue biomarkers, such as microRNAs (miRNAs), have been developed for clinical applications in recent years (1).

miRNAs are oligonucleotides of small non-coding RNA structure of 18-24 nucleotides (average 22 nt) transcribed from highly conserved DNA regions but not translated into protein. miRNAs play a crucial role in the processing, regulation and similar post-transcriptional levels of intracellular genetic information in all multicellular eukaryotic organisms (4,5,6). miRNAs are involved in numerous pathways that are critical for the cell, and therefore, when they fail to function, they may lead to susceptibility to diseases, particularly cancer (7).

There has been a recent increase in the number of studies that investigate the role of miRNAs in regulating different cellular processes such as energy production, protein synthesis, proliferation, differentiation and apoptosis (8). In the onset and progression of cancer, miRNAs act as tumor suppressors or oncogenes depending on the characters of target genes (4). Disruption of normal miRNA expression patterns has been reported in different liver diseases ranging from chronic hepatitis (CHB) to cirrhosis and HCC (9,10,11). Diagnosing people with HCC at an early stage before clinical signs and symptoms develop is an urgent need for improving prognosis (12).

The aim of this study was to determine hsa-miRNA-21-3p, hsa-miRNA-29a-3p, hsa-miRNA-122-3p and hsa-miRNA-192-5p expression levels in HBV- and HCV-related HCC and liver cirrhosis (LC) cases and their potential to become biomarkers. The miRNAs included in the study were determined by literature review. One miRNA was selected from the well-known change in liver diseases (hsa-miRNA-122-3p), while the other miRNAs were selected from miRNAs, in which studies on this subject have just begun.

Materials and Methods

Sampling Methods

The study sample consisted of 60 patients admitted to gastroenterology for treatment and follow-up and of 26 healthy volunteers. Eighteen participants had HBV-associated HCC, 15 had HBV-related cirrhosis, 8 had HCV-associated HCC and 19 participants had HCV-related cirrhosis. The study was approved by the Ethics Committee of the Sakarya University Faculty of Medicine (approval number: 71522473/050.01.04/132 and date: 28.06.2016). Written informed consent was obtained from patients prior to participation. A study group was established from patients who agreed to participate in the study based on their medical and pathology reports.

Preparation and Analysis of Samples

Blood samples were collected from participants and placed in dry gel tubes. Serums separated from the blood samples were stored at -80°C until total RNA isolation, which was, then, performed using a Direct-zol™ RNA MiniPrep (ZYMOS Research Corp., USA) kit according to the manufacturer’s instructions. cDNA synthesis and real-time polymerase chain reaction amplification from the isolate was performed using an EPIK™ miRNA Select Hi/Lo-ROX (Bioline Reagents Ltd.) miRNA amplification kit. Amplification and analysis were performed using a Rotor-Gene Q (QIAGEN, Germany).

Statistical Analysis

Data were analyzed using the Statistical Package for Social Sciences (IBM SPSS Statistics 20, USA) at a significance level of 0.05. Recently, it has been proposed that the change in gene expression in a microarray experiment will be best defined by using fold change rather than t-statistic. Fold change is the ratio of two values and measures how much of a variable changes between the two measurements. The difference in the mean obtained by taking the logarithm of the data corresponds to the proportions of the original scale (13,14).

Results

Table 1 shows some demographic and clinical data of the participants. Patients' hsa-miRNA-21-3p, hsa-miRNA-29a-3p, hsa-miRNA-122-3p and hsa-miRNA-192-5p expression levels were evaluated as multiples of those of the control group (Table 2). Hsa-miRNA-21-3p and hsa-miRNA-122-3p levels of all patient groups, except HCV-LC patients, increased 3-4 fold. hsa-miRNA-

29a-3p expression significantly decreased in patients with HCV infection (p<0.05). hsa-miRNA-192-5p increased 3-fold in HBV-LC patients (p<0.05) but showed no significant difference in other groups. hsa-miRNA-122-3p, which is a liver specific miRNA, increased in HCV-LC patients.

Discussion

HCC is an aggressive malignancy with poor prognosis and high mortality rates worldwide. It, however, does not have a reliable and effective and non-invasive biomarker. We, therefore, need new biomarkers to determine HCC early. miRNA expression levels are promising biomarkers, and therefore, are of great interest (15). However, numerous studies on CHB characterize miRNA profiles as controversial and complex.

Ebrahimifard et al. (16) showed that miRNA-122 can be used as a biomarker to detect cirrhosis associated with CHB and HBV before progressing to HCC. We also detected a more significant increase in miRNA 122-3p in the hepatitis B-related HCC and LC groups and in the HCV-related HCC group compared to the healthy control group.

Lin et al. (17) reported that miRNA-29a, miRNA-122 and miRNA-192 synthesis was 2.64, 3.13 and 2.60 times, respectively, higher in patients with HCC than in those diagnosed with CHB. Zhou et al. (18) conducted a study on plasma samples of HBV-related HCC patients and reported a 3.3-, 2- and 2.9-fold increase in miRNA-122, miRNA-21 and miRNA-192, respectively. We also detected 1.4-, 1.48-, 2.54- and 3.67-fold increase in miRNA-29a-3p, miRNA-192-5p, miRNA-122 and miRNA-21, respectively, in HBV-related HCC patients. Tan et al. (19) developed a miRNA panel for HCC diagnosis and reported that miRNA-122 and miRNA-192 synthesis was 0.27 and 0.76 times lower in patients diagnosed with HCC than in healthy volunteers.

Wang et al. (20) conducted a study on 30 patients with HCC and 30 patients with CHB and 30 healthy volunteer participants in Xinxiang, China and reported that patients with HCC had a higher serum miR-21 expression level than CHB or healthy volunteers, which is consistent with miRNA-21 values in our study (20).

Zekri et al. (21) reported that miRNA-122 and miRNA-192 expression was, respectively, 2.2 and 1.88 times higher in HCV-infected patients with HCC than in healthy volunteers. We also detected that miRNA-122 and miRNA-192 upregulation was 3.84 and 1.88 times higher in HCV-related HCC patients than in healthy participants.

Zhou et al. (18) reported that miRNA-122, miRNA-21 and miRNA-192 expression was, respectively, 1.9, 1.2 and 4.6 times higher in patients with HCC than in cirrhosis patients. Tan et al. (19) conducted a study in China and reported that cirrhosis patients had 2 and 1.2 times higher miRNA-122 and miRNA-192 levels, respectively, than patients with HCC. They also reported that miRNA-21 and miRNA-122 synthesis was, respectively, 1.6 and 3.13 times higher in cirrhotic patients than in patients with HCC.

We also detected that patients with HCC had higher miRNA-122 and miRNA-192 synthesis than cirrhosis patients. However, miRNA-21 expression was 4.7 times higher in HBV-related LC patients and 0.74 times less in HCV-related LC patients.

Bao et al. (22) conducted a study on serum samples and reported a downregulation in fibrosis-related miRNA-29 and miRNA-21 expression. We also detected a downregulation in miRNA-29a-3p expression in HBV-related HCC and LC patients, a downregulation in miRNA-21-3p expression only in HCV-related LC patients and a 1.14-fold increase in miRNA-29a-3p expression in HBV-related LC patients.

Again, Zekri et al. (21) reported a 0.45- and 1.17-fold change in miRNA-122 and miRNA-192 levels in the serum of cirrhosis patients with HBV infection than in those of healthy control group. We also detected a 0.52-fold downregulation in miRNA-122 and a 1.02-fold upregulation in miRNA-192 in HCV-related LC patients and a 2.98-fold increase in miRNA-192-5p in HBV-related LC patients.

Oksuz et al. (23) reported that miRNA-29a-3p synthesis was 2.95 times lower and miRNA-122 synthesis was 5.22 times higher in HCC patients whereas miRNA-122 synthesis was 1.38 times lower in cirrhosis patients. The results of miRNA-29a reported by Oksuz et al. (23) are different from ours. In our study, miRNA-29a synthesis was 1.41 and 0.40 times in HBV-related HCC patients and HCV-related HCC patients, respectively. miRNA-122 synthesis was 2.54 and 3.83 fold in HBV-HCC and HCV-HCC patients, respectively. miRNA-122 synthesis was 0.5-fold in HCV-LC patients.

Having conducted a study on individuals with HCV infection, Waring et al. (24) detected more than 100 miRNA species in serum and found that miRNA-122 level showed the most consistent change in all HCV genotypes in response to treatment. They also reported that miRNA-122 decreased approximately four-fold in two weeks and remained low throughout the treatment in all participants.

Tat Trung et al. (25) stated that mir-21, mir-122 and mir-192 as well as alpha-fetoprotein (AFP) are biomarkers for the diagnosis of HCC in HBV patients, and in particular in HBV-related LC patients with normal AFP levels or in HCC patients with small tumors.

Conclusion

After a quarter century of research, our knowledge of the mechanisms of biosynthesis, effect and function of miRNAs has
been greatly enhanced. Depending on the target mRNA, miRNAs act as tumor suppressors or oncogenes in cancer development. Information on miRNAs should be standardized to be able to use them as biomarkers for cancer development. According to our results, hsa-miRNA-21-3p and hsa-miRNA-122 assays can be used for HBV-HCC and HCV-HCC diseases; Hsa-miRNA-21-3p, hsa-miRNA-122 and hsa-miRNA-192-5p assays can be used for HBV-LC and MiRNA-29a-3p assay can be used for HCV-LC. Further research should be conducted to verify these results to accelerate the applicability of the assays.
