Inner Surface of Pterion in Terms of Surgical Approaches: An Anatomical Cadaveric Study

Cerrahi Yaklaşımlar Açısından Pterionun İç Yüzeyi: Anatomik Kadavra Çalışması

**ABSTRACT**

**Objective:** Aim of this study was to evaluate the morphometric features and the inner surface of the pterion in terms of surgical procedures for neighboring anatomical structures.

**Methods:** Thirty five skeletally mature craniums were included in the present study. Fifteen of the craniums were belonged to cadavers, 20 of the craniums were dry bones. All specimens were obtained from the department of anatomy. Type of pterion and distance of midpoint of pterion to palpable surface landmarks were noted. Inner surface of pterion was marked by translumination of a laser pointer. Overlap of pterion with important anatomical structures and its closest distance to them was evaluated.

**Results:** The most common type of pterion was sphenoparietal-type (80%) and the least common type was epipetrical (1.4%) type. The mean thickness of the calvaria on the pterion was 4.2±0.16 mm. Pterion is located approximately 4 cm superior and 2.5 cm anterior to midpoint of arcus zygomaticus; 3 cm superior and 1.5 cm posterior to tuberculum marginale; 7 cm superior and 6.5 cm anterior to the tip of processus mastoideus. In 61.4% (n=43) of samples, inner surface of pterion was found to be associated with groove of a. meningea media. In 81.4% (n=57) of specimens, inner projection was coincided with sinus sphenoparietalis. Foramen spinosum was located posteroinferior to inner projection and the mean closest distance was 39.8±6.53 mm. Meckel cave was located postero medial to inner projection and the mean closest distance was 40.6±3.18 mm.

**ÖZ**

**Amaç:** Bu çalışmanın amacı pterionun morfometrik özelliklerini ve pterionun iç yüzeyini, komşu anatomik yapılar için yapılan cerrahi prosedürler açısından değerlendirmektir.

**Bulgular:** Pterionun en yaygın görülen tipi sphenoparietal-tip (%80), en az gözlemlenen tip epipetrik tip pterion (%1,4) idi. Kalvaria’nın pterion üzerindeki ortalama kalınlığı 4,2±016 mm olarak ölçüldü. Pterion, arcus zygomaticus’un orta noktasına göre yaklaşık 4 cm üstte ve 2,5 cm önünde; tuberculum marginale’ye göre 3 cm üstte ve 1,5 cm arkada, processus mastoideus’a göre 7 cm üstte ve 6,5 cm onde yer alıyor olarak bulunmuştur. Örneklerin %61,4’ünde (n=43) pterionun iç yüzeyi a. meningea media’nın olduğu ile ilişkilidi. Örneklerin %81,4’ünde (n=57) ise sınuş sphenoparietalis ile çakışmaktadır. Foramen spinosum postero inferoer yerlesimde ve ortalamda en yakın mesafesi 39,8±6,53 mm idi. Meckel olguu postero medial yerlesimde ve ortalamda en yakın mesafe 40,6±3,18 mm idi.

**Sonuç:** Sınıus sphenoparietalis ve a. meningea media’nın frontal dali, pterionun iç yüzeyi ile çalşan daha anatominik yapılar vardır.

Introduction

Cranial part of the central nervous system is enclosed by neurocranium. In the adult cranium, bones form the neurocranium articulate by joining with each other via sutural joints. In the embryo, junctions of these sutural joints are not calcified. Membranes covering spaces between these junctions are called fontanelles. In human fetus, six fontanelles are found in the neurocranium. Two of them are seen on the superior of the skull which are called anterior and posterior fontanelles. Four of them are located on the lateral side of cranium. Anteriorly located ones are called sphenoid fontanelles and the posteriorly located ones are called mastoidal fontanelles (1).

In the adult, the sphenoid fontanelle becomes pterion by calcification which is the junction of the sutura on the anterolateral side of the neurocranium (1). Pterion is also known as the thinnest part of the calvaria (2). Pterion is often used as a surgical landmark especially for the transsylvian approach in order to reveal frequently seen vascular or parenchymal lesions (3,4). On the other hand, pterion is also used as marking point for the branches of a. meningea media, in terms of epidural hemorrhage during lateral craniotomies (5).

In this study, we aimed to reveal the morphometric features of the pterion and its relationship with the vascular and dural anatomical structures which is important for lateral surgical approaches.

Methods

Ethics committee approval was taken from the local ethical committee (KEAH - 2017 - 1564).

A total of forty skeletally mature adult craniums were included in the present study. Twenty of the craniums were dry bones, twenty of the craniums belonged to adult cadavers. Cadavers were obtained from the department of anatomy. Cadavers were fixed with formaldehyde and they belonged to Caucasian subjects. Age of the cadavers were unknown. Five of the craniums with fracture or previous dissection regarding pterion region were excluded from the study. A total of thirty five craniums and seventy sides (fifteen dry bones, twenty cadaveric) were included for the study.

Pterion was revealed on the lateral side of the cranium. Formation pattern of the pterional junction was noted according to the Murphy Classification which was described in 1956 (6).

Statistical Analysis

Descriptive analyses were made for all variables. Statistical results were represented as mean ± standard deviation. Student’s t-test was performed to compare the measurements of left and right
Results

The most common type of the pterion was sphenoparietal type in the present study (80%) (Figure 2A). The least observed pterion type was the epipterical type of pterion (1.4%) (Figure 2B). The frequencies of pterion types are given in Table 1. The mean thickness of the calvaria on the pterion was measured as 4.2±0.16 mm.

In order to locate pterion easily during surgeries, palpable bony landmarks were chosen. Vertical and horizontal distances between pterion and these landmarks are given in Table 2. According to our results, pterion was located approximately 4 cm superior and 2.5 cm anterior to midpoint of the arcus zygomaticus, 3 cm superior and 1.5 cm posterior to tuberculum marginale, 7 cm superior and 6.5 cm anterior to the tip of the processus mastoideus.

Inner surface of the pterion was marked by translumination from the exterior of the cranium. Relationship of the inner surface of the pterion with vascular and dural structures was observed. In 61.4% (n=43) of the samples, inner surface of the pterion was found to be associated with groove of a. meningea media (Figure 3). This relationship was associated with the frontal ramus of the a. meningea media in all of the samples. Bifurcation of the a. meningea media to frontal and parietal branches was 17.3±1.6 mm inferior to inner projection. In 81.4% (n=57) of the specimens, inner projection was coincided with sinus sphenoparietalis (Figure 3, 4). Foramen spinosum was located posteroinferior to the inner projection and the mean closest distance was 39.8±6.53 mm. Meckel cave where the trigeminal ganglion is found was located posteromedial to inner projection and the mean closest distance was 40.6±3.18 mm.

Statistical analyses of the data revealed that no significant difference was found between right and left sides (p>0.05).

Discussion

The pterion which is located on the anterolateral side of the cranium is the junction of four neurocranium bones: Temporal, frontal, sphenoid and parietal bones (1). Since inner surface of the pterion is associated with important anatomical structures such as a. meningea media or Sylvian fissure, it is commonly used as an important extracranial landmark (3). The appearance of the conjunction of the pterion varies. The most common classification used for the appearance of the pterion is the Murphy classification (6). The sphenoparietal type pterion (Type A according to Murphy Classification) is the most common observed pterion type and our findings are consistent with the literature. The rarest type of pterion varies due to ethnic differences (2,7). In the current study, epipterical type was the least observed type (Type C).
In the present study, palpable surgical procedures in neurosurgery. Due to close distance to
the anterior and middle cranial fossa are short.

The pterional approach is one of the most commonly used
intraoperatively at the parasellar region. Distance of the dural sinus to Meckel cave was found as 40.6 mm which was consistent with the previous results.

There is limited metric data about pterion and a. meningea media in the literature. The closest distance between pterion and the stem of the a. meningea media was reported to be 1 cm by Kalthur et al. (13). Ma et al. (8) reported that the branches of the a. meningea media travels within a 1 cm diameter circle around pterion. In the present study, foramen spinosum was found to be approximately 4 cm posteroinferior to pterion. The closest distance of pterion to bifurcation of the artery was found to be 1.7 cm, which was longer than the South Indian population (13). Ma et al. (8) reported that internal aspect of the pterion coincided with the branches of the a. meningea media in 68% of the samples. In the current study, in 61.4% of the samples, overlapping of the vessel with pterion was found which was lower than but similar with the previous results.

In classical anatomy textbooks, a. meningea media was reported to be overlying the inner surface of the pterion (1,11,12). Rather than the main stem of the a. meningea media, anterior or frontal ramus of the artery courses on the internal aspect of the pterion. There is limited metric data about pterion and a. meningea media in the literature. The closest distance between pterion and the stem of the a. meningea media was reported to be 1 cm by Kalthur et al. (13). Ma et al. (8) reported that the branches of the a. meningea media travels within a 1 cm diameter circle around pterion. In the present study, foramen spinosum was found to be approximately 4 cm posteroinferior to pterion. The closest distance of pterion to bifurcation of the artery was found to be 1.7 cm, which was longer than the South Indian population (13). Ma et al. (8) reported that internal aspect of the pterion coincided with the branches of the a. meningea media in 68% of the samples. In the current study, in 61.4% of the samples, overlapping of the vessel with pterion was found which was lower than but similar with the previous results.

Trigeminal ganglion is located on the impressio trigeminalis which is at the petrous apex of temporal bone. Layers of the dura mater cover this area and a space is formed between the layers of the dura mater in this region. This space is called the Meckel cave which contains trigeminal ganglion and its branches. This dural space is also in the neighborhood of the parasellar region (14). Thus, Meckel cave is an important surgical intervention area for trigeminal ganglion and cavernous sinus. Distance of Meckel cave to the inner surface of the posterior root of the arcus zygomaticus and lateral tip of the petrous ridge was reported as 26.5 mm and 38.4 mm, respectively in a previous study (14). In the current study, closest distance of internal aspect of the pterion to Meckel cave was found as 40.6 mm which was consistent with the literature.

To our knowledge, no previous study has reported the relationship of sinus sphenoparietalis with pterion. The sinus sphenoparietalis courses along the lesser wing of the sphenoid bone. During its course from posterior to medial part of sinus cavernosus; middle meningeal veins, superficial middle cerebral vein, anterior temporal diploic veins, and ophthalmic veins may be drained into sinus sphenoparietalis and larger sinuses are seen in these cases (1). A larger sinus sphenoparietalis may cause complications during pterional approaches. In the present study, overlapping of the dural sinus with inner surface of pterion was found in 81.4% of the samples.

Main limitation of our study was relatively low sample size. We believe that further studies with larger samples will provide more detailed results.
Conclusion
In conclusion, sinus sphenoparietalis and the frontal branch of the a. meningea media are the main anatomical structures overlapping with the internal aspect of the pterion. Since the metric data about the internal aspect of pterion and neighboring anatomical structures are limited in literature, we hope that percentage of the overlapping dural sinus (81.4%) and meningeal vessel (61.4%) that we showed would contribute to the literature. In order to minimize complications, these anatomical structures should be kept in mind during pterional approaches.
