Unexpected Histopathological Findings After Laparoscopic Sleeve Gastrectomy

Laparoskopik Sleeve Gastrektomi Ameliyati Sonrasinda Gorulen Beklenmedik Histopatolojik Bulgular

ABSTRACT

Introduction: The prevalence of obesity is increasing all over the world. Laparoscopic sleeve gastrectomy (LSG) has become the most common bariatric surgery in the world today. Unlike other bariatric surgeries, laparoscopic sleeve gastrectomy yields a pathological examination. The aim of this study was to describe unexpected histopathological findings following LSG.

Methods: In this study, the pathologies of 1364 patients who underwent LSG between March 2013 and September 2019 were analyzed retrospectively. Patients were evaluated by a multidisciplinary team in the preoperative period. Patients who met the criteria for LSG were operated. These criteria were; Body Mass index (BMI) ≥40 kg/m² or BMI >35 kg/m² and comorbidities or BMI between 30 and 35 kg/m² with accompanying Type 2 diabetes Mellitus or Metabolic syndrome. Two hundred four of the patients underwent gastroscopy preoperatively.

Results: One thousand three hundred sixty four patients underwent LSG. The mean age was 40.93±10.86 years; 974 patients (71.48%) were female. The mean BMI was 42.23±7.28. The most common findings in the pathologies were normal gastric specimen (50%), gastritis (30%) and changes due to proton pump inhibitor use (23%) respectively.

Conclusion: Gastroscopy should be added to the preoperative preparation process in cases where there is no gastric specimen after the operation. Preoperative gastroscopy is not a necessity for laparoscopic sleeve gastrectomy. It can be performed in selected cases.

Keywords: Laparoscopic sleeve gastrectomy, bariatric surgery, histopathological changes

ÖZ

Bulgular: Bin üç yüz altmış dört hastanın patolojisini inceliyoruz. Hastaların ortalaması 40.93±10.86 idi; 974 hastanın (71.48%) kadın olduğu. Hastaların ortalaması 42.23±7.28 idi. Patolojilerin en sık bulgusu normal mide piyesi (50%), gastrit (30%) ve proton pompa inhibitör kullanımları bağlı değişiklikler (23%) idi.

Sonuç: Sleeve gastrektomi ameliyatı sonrası beklenmedik histopatolojik bulgular saptanabilir. Ancak ameliyat öncesi yapılan gastroskopi ile saptanması zordur. LSG ameliyatı sonrasıda böyle bir zorunluluk olmayıp seçilmiş olgularda ameliyat öncesi dönemde uygulanabilir.

Anahtar Kelimeler: Laparoskopik sleeve gastrektomi, histopatolojik değişiklikler, bariatrik cerrahi

Introduction
The incidence of obesity is increasing worldwide. More than one billion adults are thought to be obese or overweight. Obesity is associated with many diseases, including low life expectancy and arterial hypertension, hyperlipidemia, type 2 diabetes mellitus (T2DM) (1-3).

Bariatric surgery is the most effective technique to improve comorbidities associated with weight loss and obesity (4). Today, laparoscopic sleeve gastrectomy (LSG) is the most commonly applied bariatric surgery for obesity and associated comorbidities in the United States and Asia-Pacific region, with its relative ease of application and excellent results (5,6). Unlike Roux-en-Y gastric bypass, a specimen is removed that can be pathologically examined and unexpected pathological results can be encountered.

In most of the previously published series, it was reported that upper gastrointestinal system endoscopy was performed preoperatively, and fewer studies reported that there were few or no endoscopic examinations (7-11). However, this issue is still controversial. Although The American Association of Gastrointestinal and Endoscopic Surgeons and The American Gastrointestinal Endoscopy Society recommend preoperative endoscopy in patients with gastrointestinal symptoms, it is recommended to be performed routinely for all patients that will undergo Roux-en-Y gastric bypass because it is difficult to reach remnant stomach postoperatively (12). Similarly, The American Association of Metabolic and Bariatric Surgeons (ASMBs) recommends gastroscopy only in clinical necessity in the preoperative period (13).

The aim of this study is to identify unexpected histopathological findings following LSG.

Methods
Pathology reports of patients were retrospectively analyzed to identify all consecutive patients with morbid obesity who underwent LSG between March 2013 and September 2019. All patients were evaluated as suitable for bariatric surgery based on The American Association of Clinical Endocrinologists, The Obesity Association and ASMBs guidelines. Written and verbal surgical informed consent form was obtained from all patients before surgery. Approval was obtained from the ethics committee of Liv Hospital Ulus on 09.08.2019 for this study (decision no: 2019-23).

Patients meeting the following criteria were considered eligible for LSG:
Patients with Body Mass index (BMI) ≥40 kg/m² or BMI > 35 kg/m² and accompanying comorbidities or BMI between 30 and 35 kg/m² and with accompanying T2DM or metabolic syndrome were operated. Patients other than these criteria were not included. Patients who underwent revision surgery and those who underwent different bariatric procedures were not included in the study.

All patients were evaluated by a multidisciplinary team consisting of a cardiologist, endocrinologist, dietitian, psychologist, pulmonologist and anesthesiologist before surgery. All patients underwent blood tests and a chest X-ray; Abdominal ultrasonography (abdominal pain and/or suspected cholecystitis history) and gastroscopy were also performed in patients who were deemed necessary (reflux, suspected hiatal hernia, upper gastrointestinal system complaints, dyspepsia, family history of malignancy). All patients were examined macroscopically and histopathologically.

Statistical Analysis
In the statistical analysis of all data, IBM SPSS (Statistical Package for the Social Sciences) Statistics for Windows, Version 22.0. Armonk, NY: IBM Corp. was used. Mean and standard deviation values were calculated in the descriptive statistics of the data.

Results
Between March 2013 and September 2019, 1425 patients underwent different types of bariatric surgery and 1364 patients who underwent LSG were included in this study. Sixty one cases who were not included in the study were other bariatric surgeries or revision surgeries. The mean age was 40.93±10.86 years; 974 patients (71.48%) were women. The mean BMI was 42.23±7.28.

Most histopathological examinations of the specimens (682 patients, 50%) resulted in normal stomach tissue. The subsequent pathologies were gastritis (409 patients, 30%) and changes due to proton pump inhibitor (313 patients, 23%), respectively. Pathologies following them in decreasing rates are Helicobacter pylori (HP) infection (477 patients, 35%), intestinal metaplasia (20 patients, 1.5%), fundic gland polyp (5 patients, 0.36%), gastrointestinal stromal tumor (GIST) (6 patients, 0.44%), Schwannoma (1 patient, 0.073%), heterotopic pancreatic tissue (1 patient, 0.073%), duplication cyst (1 patient, 0.073%), and neuroendocrine tumor (1 patient, 0.073%) (Table 1). When the age distribution of tumoral results was evaluated, the patient diagnosed with Schwannoma was 49 years old and the tumor diameter was 0.4 cm. In the patients in the GIST group, 2 patients were 45 years old and their tumor diameters were 0.6 and 0.5 cm. One patient was 49 years old and tumor diameter was 1 cm; One patient was 64 years old and tumor diameter was 1.2 cm; one patient was 55 years old and tumor diameter was 0.7 cm; one patient was 56 years old and the tumor diameter was 0.7 cm. The patient with a neuroendocrine tumor was 48 years old and the tumor diameter was 1.2 cm.

Patients with macroscopically detected pathology during surgery underwent gastroscopy in the surgery. No pathology was found within the lumen.

In the existing cases, no additional treatment was required in the postoperative period. During the preoperative preparation period, 204 (15%) patients with gastrointestinal system complaints underwent gastroscopy. Medical eradication was not routinely applied to the patients with \textit{HP} infection.

**Discussion**

After the increasing frequency of LSG in recent years, different histopathological results have begun to appear in gastric specimens. This resulted in an increase in parallel with incidental findings. Although these findings may cause the surgeon to change the way of treatment in the postoperative period, most of the reported diagnoses do not require further clinical follow-up (14). In our series, there was no patient requiring treatment change in the postoperative period.

Some findings may vary according to geographic distributions. For example, the frequency of \textit{HP} infections can vary from 3.2% to 64% (15-19,10,20-23). This rate was 35% in our series. Lee et al. (24) have shown that eradicating \textit{HP} may reduce the risk of long-term malignancy, but this issue is still controversial. We did not apply routine eradication to patients who did not have clinical complaints among those with \textit{HP} infection in our clinic.

Neoplasia was a rare finding in both our study and previous studies. While the frequency of GIST ranges from 0 to 1.2% (10,11,15,16,19,20,25) in the literature, we found 0.44% in our series. We detected all of these patients during the surgery and there was no need to change the treatment and follow-up protocol both in the surgical technique and in the postoperative period. All of them were early stage stromal tumors with low mitosis rate and low ki67 index. As in the study of Raess et al. (16), these incidentally detected histopathological findings gain more importance in surgical interventions that do not allow upper gastrointestinal system endoscopy in the future and in cases without stomach specimen. Routine gastroscopy in the preoperative period in LSG is a controversial issue. While a group of researchers advocated the necessity of performing routine gastroscopy to each patient preoperatively (26), another group shows a more conservative approach before LSG (27). The fact that we did not encounter any pathology in the gastric lumen in gastroscopy that we performed during the surgery for the lesions we detected incidentally on the stomach wall. This result questions the necessity of preoperative endoscopy.

In our series, we selectively applied upper gastrointestinal system endoscopy in 1364 patients in the preoperative period, as suggested by ASMBM (13), who had suspected hiatal hernia, family history of malignancy, and severe upper gastrointestinal complaints. We performed preoperative endoscopy only in 15% of patients.

We decided to perform Roux-en-Y gastric bypass instead of LSG upon the detection of grade C esophagitis according to the Los Angeles classification in only one of the patients who underwent gastroscopy in the preoperative period. LSG was applied to all other patients and a routine follow-up protocol was applied in the postoperative period. Although Safaan et al. (19) found an increase in abnormal pathologies detected with increasing age, we did not find any findings increasing with age in our series.

**Conclusion**

Preoperative endoscopy should be routinely performed especially in the types of surgery where endoscopic examination cannot be performed after surgery and a gastric specimen will not be removed. However, preoperative endoscopic evaluation is sufficient only in selected cases for LSG, since it does not cause much change in the decision of the type of surgery or in the postoperative follow-up.

**Ethics Committee Approval:** Approval was obtained from the ethics committee of Liv Hospital Ulus on 09.08.2019 for this study (decision no: 2019-23).

**Informed Consent:** Written and verbal surgical informed consent form was obtained from all patients before surgery.

**Peer-review:** Externally peer-reviewed.
