ABSTRACT
Introduction: Medication non-adherence is one of the major problems in treating patients with depression. Non-adherence results in an increased risk of relapse and reduced quality of life. The objective of this study was to review and summarize studies on the factors associated with antidepressant medication non-adherence in patients with depression.
Methods: Literature searches were performed using PubMed/Medline and Google Scholar. The search was limited to English language articles published in journals between January 2000 and December 2019. Studies that analyzed factors of non-compliance in patients with depressive disorder were included.
Results: Patient-related factors like forgetfulness, comorbidity, and misconception about the disease and medication, medication-related factors, polypharmacy, side effects, pill burden and cost, health care system-related factors, including physician-patient interaction, social-cultural factors like religious and cultural beliefs and stigma, and logistic factors were found to be the major factors associated with antidepressant non-adherence.
Conclusion: Efforts should be made to increase patient adherence by strengthening physician-patient relationships, simplifying medication regimens, and rectifying myths and beliefs held by patients with scientific information and explanations, to increase antidepressant non-adherence.

Keywords: adherence, antidepressants, depression, associated factors

INTRODUCTION
Depression has become a major public health concern, with increased prevalence and global disease burden, due to associated mental as well as social and interpersonal disability. According to the World Health Organization (WHO), by 2020, it will be the second-highest known cause of worldwide disability. It is characterized by a sad mood, pessimistic thought, lowered interest in day-to-day activities, poor concentration, insomnia or increased sleep, significant weight loss or gain, decreased energy, continuous feelings of guilt and worthlessness,
decreased libido, and suicidal thoughts occurring at least once in two weeks \(^1,^3\). Antidepressant drugs are the most effective and widely used forms of treatment for depression \(^4\). Despite the availability of many effective antidepressants, 50% of patients do not achieve a complete cure of symptoms and even experience recurrence \(^5,^6\). Therefore, in many patients, depression becomes a chronic disorder and may require lifelong antidepressant treatment. For the desired outcome of treatment, adherence to antidepressant medication plays a crucial role, and non-adherence is the major problem associated with antidepressant treatment. Adherence has been defined as ‘the extent to which a person’s behavior regarding taking medication, following a diet, or executing lifestyle corresponds with recommendations from a health care provider’ \(^7\). The failure of patients to follow medical advice results in a risk of relapse and reduced quality of life. Many factors like patient factors, medicine related factors, health system, and social and cultural factors are associated with patients being non-adherent to prescribing antidepressants. Hence, this study was conducted to review and summarize studies about the factors associated with antidepressant medication non-adherence in patients with depression.

METHODS
Data Sources, Search, and Selection
A comprehensive literature review was conducted using PubMed Medline and Google Scholar. The search was limited to English language articles published in journals between 2000 and 2019. Keywords used were: depression, depressive patients, antidepressant, antidepressant adherence, patient compliance, and discontinuation of antidepressants. We also included articles listed in the author’s reference lists and those listed in other systematic reviews. Studies were selected based on relevancy. Full articles on those studies which deemed relevant to our study title were fully reviewed and irrelevant studies were eliminated.

Study selection

...
For inclusion in our review, studies need to include adult or elderly patients irrespective of gender diagnosed with depression and prescribed antidepressants by physicians. Literature can be of varying methodologies i.e. observational, prospective, cross-sectional, retrospective, or survey.

Our study outcomes were the factors that caused non-adherence to antidepressants among patients with depressive disorder. Studies that did not meet our criteria were excluded during the review. Studies were discarded if they were clinical trials and reviews.

**RESULTS**

One hundred and fifty-five articles were selected by title/abstract, and finally 21 were included. The total sample size was 66,148 patients. Two studies were performed in Ethiopia, one in Nepal, Malaysia, Island, two in China, two in India, one in Saudi Arabia, two in Spain, one in Italy, three in the United States, one in the UK, one in Korea, one in Japan, one in Pakistan, and one in New Zealand. Sample sizes were less than 100 in four studies, 100–400 in fifteen studies, and more than 20,000 in two studies. Table 1 shows the main findings of these studies.

antidepressants in primary care. Beliefs about Medication Questionnaire (BMQ) and Medication Adherence Report Scale (MARS) were used.

Yeh et al., 2008<sup>27</sup> To determine predictors of medication adherence among patients with depression. Cross-sectional study n=181 age: 23-61 years The self-report questionnaire used to collect data.

Ashton et al., 2005<sup>28</sup> To identify reasons for discontinuation and noncompliance with antidepressant medications. Survey n=344 age: 18-65 years A 42-question survey was used.

Predictors for adherence: treatment efficacy, the severity of depression, mental health professional-patient interaction, understanding the need to continue taking medication, social support, and patient income. Negative beliefs and perceptions decrease medication adherence.

60% discontinued treatment with an antidepressant agent. The main reason for discontinuation of treatment: having trouble in remembering to take the drug, followed by weight gain, unable to have an orgasm and, lost interest in sex.

**DISCUSSION**

**a. Sociodemographic factors**

From this review, it was observed that the majority of the patients who were non-adherent to their prescribed antidepressants were younger patients aged <40 years<sup>15, 21, 23</sup>. Non-adherence among younger patients could be due to having less experience with depression and associated medications. In contrast, older patients may have more experience with depressive episodes and antidepressants, which makes them more willing to complete their prescribed doses<sup>15, 23</sup>. Additionally, antidepressants are associated with common side effects like weight gain and impaired sexual function, which may be troublesome to younger patients to adhere to antidepressant drugs<sup>15, 21, 23, 29-31</sup>. Female patients were found to be more non-adherent to prescribed antidepressants than males<sup>19, 23, 24, 32</sup>. Women play multiple roles in the family and society, such as, homemakers, spouses, mothers, professionals, and caregivers, which might cause them difficulty visiting the hospital and making them unable to adhere to their prescribed medications. However, findings contrary to these studies were reported by the work<sup>12</sup> and<sup>14</sup>, where males were more non-adherent to their regimen. This could be due to they were not permitted leave from office of they may be concerned about the deduction of payment on that particular day they took leave for visiting the hospital. Their inability to make hospital visits in their working days might have kept them away from being adhered to their treatment, <sup>12, 14, 19, 29, 33</sup>. One of the study<sup>14</sup> showed that non-adherence and higher level of education are inversely proportional to each other. This means that when the level of education increases, adherence increases, and vice versa. Highly educated people fear about side effects and long-term effects of
the drugs, which might be due to their little knowledge about disease and drugs prescribed to
them and their unwillingness to communicate with their healthcare personnel. Many studies predicted people of low socioeconomic status to be more non-adherent to antidepressants. This could be due to unemployment or unstable income, they can’t afford medicines for a long term, and frequent appointments with their physician become expensive for them, which leads to premature discontinuation and non-adherence to drug regimens. In contrast, a work found that patients belonging to high socioeconomic status were more non-adherent to antidepressants. This could be due to higher-income people have high social status and education level. They might be more concerned about the side effects or dependence potency of antidepressants, which finally leads to decreased adherence.

b. Patient-related factors
From the literature review, patients often forgetting to take their medications was found to be a common patient-related factor for antidepressant non-adherence. Also, inappropriate intake of medication or patient carelessness are the reasons for non-adherence. Patients have wrong beliefs about the disease itself or prescribed antidepressants. From the findings of our review, poor understanding of mental illness and medication was found to be the main barrier to depression treatment and hence adherence. Even after being diagnosed with depression, many did not consider themselves as having a mental illness. They believe they could easily overcome their mental illness on their own. They also believe that it would be resolved by having a positive thinking or complete rest without taking antidepressants. Some people take depression as a normal part of their aging process, some even blame it as a result of their unlucky life, or weak personality rather than a mental illness. The majority of patients taking antidepressants have misconceptions about antidepressants. They think that there is no need to take medicine in the absence of any signs or symptoms. They believe they can take less medicine or simply discontinue the medication themselves when they feel better.

The patient’s decision on adhering to antidepressants mainly depends on the balance between necessity and concern about the safety and efficacy of prescribed medicine. So many people believe that long-term use of antidepressants is toxic and may lead to kidney damage. They are also concerned with the additive and psychological dependence potential of antidepressants, all of which affect their adherence to treatment. Patients with a positive attitude towards their disease and medication and awareness of their illness adhere more to their regimen. They believe they will return to normal functioning, continuing the medications. They will communicate regularly with their physicians to enhance their knowledge about their mental illness and medication. This all will help them cope with the response and lead to better health outcomes.

Comorbidity, polypharmacy, and non-adherence are inter-related to each other. Comorbidity increases the number of medications be taken by patients. Patients will feel pill burdens and even the economic burden since they have to take different types of medications. The complex dose schedule and the intention to save the cost may force patients to discontinue their medication, leading to non-compliance. Comorbidity also leads to logistic problems, as patients have to seek medical advice from more than one physician, getting appointments, and timely medication refills time and again.
c. Medication-related factors
It is evident from many literatures, that the majority of patients deny to continue antidepressants due to the prevalent side effects of the drug prescribed \(^9, 11, 13, 18, 25, 26, 28\). Patients mostly prefer medications that have a lower risk of weight gain, sexual dysfunction, and tiredness \(^28\). Antidepressants are reported to cause many adverse effects like sedation, restlessness, tremor, dry mouth, decreased libido, weight gain, irregular menstrual cycles, and impotence. These unpleasant effects may impair patient quality of life and self-esteem, resulting in non-adherence to prescribed antidepressants \(^46, 47, 48\). Two of the studies \(^17 \text{ and } 24\), patients prescribed with antidepressants other than selective serotonin reuptake inhibitors (SSRIs) were more likely to be non-adherent. This might be due to the lower side effect profile, low overdose-related cardiotoxicity, better tolerability, and overall favorable risk-benefit ratio attributed to SSRIs \(^11, 49-52\).

Adherence to treatment is greatly influenced by physician-patient interactions. One of the common reasons for non-adherence was the failure of physicians to provide adequate information on patients’ illness and medications prescribed \(^9, 15, 21, 25, 27\). From the studies, the most common complaint of patients found was: physician not explaining the timing and dose of medication completely along with the benefit of therapy, and consequence of non-adherence \(^21\). Similarly, not trusting the physician and dissatisfaction with the physician and their prescribed medication also leads to patients being non-adherent to the treatment \(^10, 15, 23, 54, 55\). Due to multiple prescribers, problems in communicating with physicians, frequent follow-up, long waiting times in hospitals, repeated medication refills, and unavailability of prescribed medications \(^19\), many patients choose to discontinue their medications \(^9, 10\). Patients lose confidence in their physician when there are multiple prescribers, which ultimately affects their medication-taking behavior. Some patients alter/stop their medication without informing their physician as they find it difficult to communicate with them. To avoid long waiting times, patients skip their appointments, leading to an insufficient amount of medication at home \(^10\).

d. Sociocultural factors
Lower adherence to medication depends on the perception of the patient about his illness, which may differ by their religion and culture they belong to \(^13, 56\). A study \(^10\) collected the beliefs of people from different religions and cultures. It stated that people from Malaysia believe that mental illness as a social punishment for the particular people, or as an illness of the soul caused by the weakness of the spirit. Similarly, Chinese people believe that mental illness is a symbol of lack of self-worthiness, which is measured in terms of education and monetary gain that brings honor to the family. Likewise, the Indians believe that one gets a mental illness from the evildoers \(^57\). All of these beliefs create barriers in pursuing and sticking to antidepressant regimens. Some patients want to experiment whether being prayerful will cure their depression, which forces them to stop taking the medication \(^10, 13, 38\). Depression is still considered a social stigma. Many regard it as a sign of a personal weakness \(^26\). Regular social support and motivation from family members and co-workers help depressive patients get going their antidepressant treatment \(^22, 27, 58\). Due to fear of being stigmatized by society, many patients do not reveal their mental illness \(^22\), which influences their adherence to medication. Unsupportive family members and co-workers also discourage patients from continuing their medication \(^10\), which further makes their mental illness severe.

e. Logistic factor
Many patients who live far from city areas or hospitals have poor access to healthcare facilities and hence hinder patients from adhering to antidepressants \(^9, 11\).
CONCLUSION
From our review, we conclude that patient-related factors like forgetfulness, comorbidity, and misconception about the disease and medication, medication-related factors, polypharmacy, side-effects, pill burden and cost, healthcare-system related factors, including physician-patient interaction, sociocultural factors like religious and cultural beliefs and stigma, and logistic factors are the major barriers to antidepressant adherence. Hence, efforts should be made to increase patient adherence by strengthening physician-patient relationships. Physicians should emphasize patient education that includes an explanation of drug, dose, duration, and timing of administration, possible side effects, adverse effects, lag time before the onset of treatment and relief of symptoms, and consequence of non-adherence. In the case of comorbid conditions, physicians should make the medication regimen simple. Additionally, they should focus on rectifying the myths and beliefs held by patients with scientific information and explanations.
