Brain Abscess in a Patient with Osteopetrosis: A Rare Complication

Running title: Brain abscess in a patient with osteopetrosis

What is already known on this topic?
The most common infectious complication of osteopetrosis is osteomyelitis; in particular, mandibular osteomyelitis may be seen due to bone sclerosis and reduced vascular supply. Otolaryngological complications, such as recurrent otitis media, are also seen frequently.

What this study adds?
To our knowledge, this report is only the second published description of brain abscess in association with osteopetrosis. Therefore, routine otologic examination should be an integral component of management and plays an important role in preventing more severe complications, such as brain abscess.

Abstract
Brain abscess formation is extremely rare in patients with osteopetrosis. Herein, we report a case of viridans streptococci brain abscess in an immunocompromised child diagnosed with osteopetrosis. The patient presented with a sudden change in mental status and convulsions. Radiological evaluation revealed a temporal lobe brain abscess, and intravenous antibiotic therapy was started immediately. The patient underwent abscess drainage, and laboratory investigation of pus material revealed viridans streptococci.

Keywords: Osteopetrosis, chronic otitis media, brain abscess, viridans streptococci

Introduction
Osteopetrosis describes a group of rare genetic skeletal disorders characterized by reduced osteoclast activity, which results in defective bone resorption and increased bone mass and density (1). Osteopetrosis classically classified descriptively by its clinical severity and inheritance pattern (2,3). The adult (autosomal dominant) type, a mild form of the disease characterized by normal life expectancy; and the infantile (autosomal recessive) type, characterized by diagnosis in early life and fatal prognosis. The intermediate type of osteopetrosis, which is a subgroup of the autosomal recessive type, is seen less frequently; diagnosis is made during early childhood, with patients being clinically normal at birth (2-4). Nowadays by the improvement in molecular and genetic techniques, osteopetrosis forms can also classified according to their genetic basis (2,3). In autosomal recessive osteopetrosis, loss of bone marrow causes anemia, thrombocytopenia and leukopenia, in turn resulting in extramedullary hematopoiesis, hepatosplenomegaly and recurrent infection. Fractures, minor trauma and osteomyelitis, especially of the long bones and mandible, may also be seen (1). Differential diagnosis of osteopetrosis including dysostosis hereditary, which is more rare and distinguished from it by the presence of early acquired sclerotic platyspondyly and metaphysical expansion. Another differential diagnostic tool is mutation analysis (3).

The factors associated most strongly with the appearance of infectious complications in osteopetrosis are impaired resistance to infection due to neutropenia and reduced vascular supply to the bone, which limits the availability of antibiotics in the infected area. Otolaryngological complications, such as recurrent otitis media, are also seen frequently, but brain abscess formation due to recurrent otitis media is extremely rare. Herein, we discuss a case of viridans streptococci brain abscess in an immunocompromised child with osteopetrosis. To our knowledge, this report is only the second published description of brain abscess in association with osteopetrosis (6).

Case Report
A 14-year-old boy with a previous diagnosis of autosomal recessive osteopetrosis type 7 (OPTB7) presented to our pediatric emergency care unit with complaints of confusion, sudden abnormal involuntary muscle contractions, and temporary cessation of breathing and cyanosis. He had experienced nausea, vomiting and diarrhea for the past 2 weeks. There was no history of trauma or fever. The patient had taken oral antibiotics, primarily amoxicillin/clavulanic acid, on numerous occasions in the past year for recurrent suppurative otitis media. He had a history of frequent purulent otorrhea, which had...
The Glasgow Coma Scale (GCS) score was 8 (E 2, V 2, M 4). Intravenous midazolam was started immediately to control seizures. Laboratory examination revealed a white blood cell count of 17,500/mm³ (80% neutrophils, 20% lymphocytes), hemoglobin level of 8.5 g/dl, platelet count of 456,000/mm³, and C-reactive protein level of 9.2 mg/dl. Serum electrolytes, renal function and liver function were all normal. Cranial computed tomography revealed a brain abscess in the right temporal lobe. The patient was prescribed intravenous ceftriaxone (100 mg/kg/day in two doses), vancomycin (60 mg/kg/day in four doses) and metronidazole (30 mg/kg/day in three doses). Dexamethasone was also started for brain edema, and levetiracetam was started to control the seizures.

On the fourth day of treatment, the patient was referred to our clinic for evaluation by pediatric infectious disease specialists. He was conscious on physical examination, with symmetrically and equally reactive pupils and no meningial sign or respiratory problem; he showed agitation. There were accompanying exophthalmus, left facial paralysis and purulent otoscopy. He had locomotor difficulties and can speak a few simple words with hearing loss. Hepatosplenomegaly also detected. His height was 96 centimeters (-8.89 SD), while his weight was 15 kilograms (-6.65 SD), respectively. Contrast-enhanced magnetic resonance imaging of the brain showed a multiloculated lesion with perilesional edema and slight contrast enhancement in the right temporal lobe (approximately 6 × 5 × 4.5 cm in diameter); subfalcine herniation and uncal herniation were also seen (Figure 1). Postintubation plain chest radiography showed diffuse increased bone density and callus formation due to fracture healing (Figure 2).

The patient underwent abscess drainage via temporal-lobe burr-hole craniostomy under general anesthesia. Yellowish-brown pus was aspirated from the affected region and the abscess was excised completely. The abscess was grey-brownish, rigid and filled with a necrotic material (7 × 5.8 × 0.9 cm in diameter). The abscess material was sent to the laboratory for microbiological and histopathological investigations. Gram staining showed gram-positive cocci and surgical drainage culture showed the growth of viridans streptococci sensitive to β-lactam antibiotics. The histopathology report revealed active chronic inflammation, including abscess formation, proliferating blood vessels, congestion and fibrosis, suggestive of pyogenic, intracerebral abscess formation. After surgery, the patient was followed in our pediatric intensive care unit (PICU) with respiratory support. He had an unfavorable clinical outcome, dying within 24 hours of admission to the PICU.

Discussion

The classification of osteopetrosis is challenging due to variability in the severity of clinical manifestations, genetic factors and associated complications. Disease severity ranges from the occurrence of life-threatening complications in neonates to incidental findings of osteopetrotic features on plain radiography in adults with no complaint (8). Mutations in tumor necrosis factor receptor superfamily member 11A (TNFRSF11A) are associated with osteoclast-poor forms of autosomal recessive osteopetrosis by interfering the interaction between RANK (encoded by TNFRSF11A) with RANK ligand (encoded by TNFSF11) which is important in osteoclast differentiation also in the immune system function (2,3,7,9). Our patient had blindness caused by optic nerve compression, multiple fractures of the extremities and hypogammaglobulinemia. He was being followed by physicians from another center under a diagnosis of osteoclast-poor with immunoglobulin deficiency, autosomal recessive, infantile form of osteopetrosis (OPPB1).

The most common infectious complication of osteopetrosis is osteomyelitis; in particular, mandibular osteomyelitis may be seen due to bone sclerosis and reduced vascular supply. Dental abscess formation and tooth decay are the main predisposing factors for infection (8,10,11). Recurrent otitis media is another important and commonly seen entity (10,11). Abnormal temporal bone anatomy, such as poor mastoid pneumatization and Eustachian tube narrowing, increases the risk of otologic infection (11).

Hypogammaglobulinemia due to bone marrow failure can also occur in patients with osteopetrosis and is an important risk factor for recurrent infection (1,2,13). In one study, 15 of 32 patients with autosomal recessive osteopetrosis experienced multiple episodes of otitis media (11). Our patient had a history of recurrent supplicative otitis media attacks in the past year, and physical examination revealed purulent otoscopy. The most common infections preceding brain abscess formation in children were sinustitis (36.3%), periorbital/orbital cellulitis (16.1%), otitis media (13.5%) and meningitis (11.9%) (14). Brain abscess formation should be suspected in patients with osteopetrosis, although only one case has been reported in the literature (1). This rare clinical entity can occur after antibiotic therapy for otitis media episodes.

Brain abscess is an aggressive and life-threatening infection with a high fatality rate, especially among immunocompromised children; furthermore, a low GCS score at presentation is associated with a poor outcome (14). Our patient was immunodeficient and had a low GCS score at presentation. The clinical picture of brain abscess can be confusing and uncertain in the early phase of the disease. The initial symptoms are typically nonspecific, and few patients show the classic triad of headache, fever and focal neurological deficits. In particular, brain abscesses should be included in the differential diagnosis of immunocompromised patients with headache, altered mental status, vomiting, seizures, focal neurological deficits, and speech and visual disturbances (14).

The only effective treatment known for osteopetrosis is allogeneic bone marrow transplantation. Historically, the best outcomes have been achieved by using bone marrow from a genotypically human leukocyte antigen (HLA)-identical donor (2,3,15). Acute or chronic otitis media episodes are seen in half of all patients with osteopetrosis, the majority of whom require the insertion of tympanostomy tubes (10,11). In our case, the patient had a history of chronic otitis media in the past year without appropriate treatment. The etiology of osteopetrosis is thought to be related to a contiguous mutation of infection.
Therefore, routine otologic examination should be an integral component of management and plays an important role in preventing more severe complications, such as brain abscess.
