Abstract

Objective: The aim of this study was to report the incidence of complications in otitis media and to determine the frequencies of various extracranial and intracranial complications at a tertiary care hospital.

Methods: We retrospectively reviewed the clinical records of patients of all ages and genders who were treated in a tertiary care hospital in Nepal from May 2015 to May 2020 for complications of acute and chronic otitis media. The complications were broadly classified as extracranial and intracranial. The details of patient profiles, histories, examination findings, investigations and treatments were reviewed from the charts.

Results: The mean age of 164 patients with complications of otitis media was 47.4±18.58 years. There were 79 (48.2%) male and 85 (51.8%) female patients. The overall incidence of otitis media complications was 0.78%. The incidences of the complications from acute otitis media, chronic otitis media without cholesteatoma, and chronic otitis media with cholesteatoma were 0.5%, 0.06% and 5.6%, respectively. Extracranial complications, intracranial complications and combined extracranial and intracranial complications were seen in 80%, 11% and 9% of the patients, respectively. The most common extracranial and intracranial complications were subperiosteal abscesses and brain abscesses, respectively. There was one mortality due to complication.

Conclusion: The incidences of complications and mortality from otitis media have declined with the availability of suitable antibiotics, improved imaging, and multidisciplinary management. Antibiotic resistance and masking of signs and symptoms, however, could pose challenges in the future.

Keywords: Otitis media, middle ear, infection, cholesteatoma, complications

Introduction

Otitis media is the inflammation of the mucoperiosteal lining of the tympanomastoid compartment. The term complication denotes the spread of the infection beyond the mucosal lining of the middle ear cleft (1). Complications of otitis media could be life-threatening with significant morbidity and mortality.

The complications of otitis media have been classified as intracranial and extracranial (2). They can occur secondary to acute or chronic otitis media with or without cholesteatoma. The prevalence rates of extracranial and intracranial complications are reported to range from 0.69% to 5%, and the rate of mortality from intracranial complications as 8% (2).

Complications of otitis media are a common problem in developing countries (3). The factors responsible for such complications in developing countries could be poverty, lack of education, unavailability of healthcare facilities and ignorance about aural symptoms. In developed countries, however, complications can be caused by antibiotic resistance, masking of symptoms by antibiotics and change in the virulence of causative organisms (4).

The purpose of this study was to report the incidence of complications of otitis media and to determine the frequencies of various extracranial and intracranial complications at a tertiary care hospital.

Methods

A retrospective study was conducted in the department of Otorhinolaryngology of Tribhuvan University Teaching Hospital, Nepal from May 2015 to May 2020. During this study period, 20,797 patients were diagnosed with acute and chronic otitis media. Out of the 20,797 patients, 164 were diagnosed with a complication and their charts were retrospectively reviewed. Ethical approval was obtained on 7th January 2020 from the Institutional Review Committee of Institute of Medicine, Tribhuvan University with protocol number of 278(6-11)E2 076/077. The study was conducted as per the ethical principles described by the Declaration of Helsinki. Informed consent was obtained from all patients.
Patients of all age groups and genders with a complication of otitis media were included in the study. Complications from acute otitis media were identified in 34 patients, complications from chronic otitis media with cholesteatoma were identified in 123 patients, and complications from chronic otitis media without cholesteatoma were observed in seven patients. The details of patient profiles, histories, examination findings, investigations and treatments were reviewed from the charts. We used Microsoft Office Excel (Microsoft Corp.; Redmond, WA, USA) for data recording and analysis.

The complications of otitis media were classified as extracranial and intracranial. Extracranial complications were mastoiditis, mastoid abscess, mastoid fistula, Bezold’s abscess, Luc’s abscess, zygomatic abscess, facial nerve paralysis, labyrinthitis and labyrinthine fistula. Intracranial complications were meningitis, brain abscess, extradural abscess, subdural abscess, lateral sinus thrombophlebitis and otitic hydrocephalus.

**Results**

During the five-year study period, 164 patients were diagnosed with complications of otitis media, of whom 79 (48.2%) were male and 85 (51.8%) were female. The incidence of complications from otitis media was 0.78%. The incidences of complications from different types of otitis media are shown in Table 1.

The age of the patients with complications ranged from seven months to 89 years, with a mean age of 47.44±18.58 years. The mean age of patients with complications from acute otitis media was 23.76±19.68 years. Complications of otitis media were more common in young patients (0 to 20 years) as shown in Figure 1. Similarly, acute otitis media complications were more common in the younger age group (0 to 10 years) as shown in Figure 2. The distribution of extracranial and intracranial complications according to age groups are shown in Tables 2 and 3, respectively.

Among the 164 patients, 155 extracranial complications and 27 intracranial complications were identified. Fifteen out of 164 patients (9%) had more than two complications. The most common co-existing complications were facial palsy and acute

AOM: Acute otitis media; COM: Chronic otitis media

**Main Points**

- The incidence of complications of acute and chronic otitis media was found to be 0.78%.
- The incidence of complications from acute otitis media has declined with antibiotic use in comparison to the incidence of complications from chronic otitis media.
- The highest incidence of complications was seen in patients aged younger than 20 years.
- The incidence of intracranial complications has declined in comparison to that of extracranial complications.
- Clinicians should be vigilant about the possibility of multiple complications in a single patient.
mastoïdite. Cependant, un patient avait quatre complications ensemble incluant mastoïdite, méningite, abcès temporal et thrombose veineuse latérale.

La complication extracraniale la plus courante était l’abcès sous-œdème, suivie de la mastoïdite et de la paralysie faciale. Il y avait 36 cas d’abcès mastoïdien, 2 cas d’abcès de Bezold et 1 cas de Luc et abcès zygoïdien (Tableau 4).

Il n’y avait que trois complications secondaires à l’otite aiguë et à l’otite chronique sans cholesteatome extra-craniale. Trois patients sur 34 avec complication de l’otite aiguë ont des complications multiples (une paralysie faciale et labyrinthite, et deux paralysie faciale et mastoïdite). Deux de ces patients avaient de diabète mellitus en conséquence. La moitié des patients avec complication de l’otite chronique sans cholesteatome avaient deux complications co-existentes et étaient paralysie faciale et mastoïdite (Tableau 4).

Tous les 27 complications intracrâniales avaient été de l’otite chronique avec cholesteatome. L’abcès cérébral était la complication intracrâniale la plus commune. Huit patients avaient un abcès cérébral en
the temporal lobe, four had in the cerebellum, and one had multifocal brain abscess (Table 5). All three patients with lateral sinus thrombophlebitis had multiple complications (one had facial palsy, one had cerebellar abscess, and one had meningitis, mastoiditis, and temporal lobe abscess).

Of the 164 patients with complication, there was one mortality (0.6%). The case was a 51-year old male with chronic otitis media with cholesteatoma. He was a known case of diabetes mellitus with stage four chronic kidney disease on dialysis. He had grade three facial palsy with lateral sinus thrombophlebitis. The patient expired on third post-operative day following canal wall down mastoidectomy.

### Discussion

Complications of otitis media can lead to various morbidities and sometimes prove lethal. In the pre-antibiotic era, the mortality from complications of otitis media was reported to be as high as 80%. Survival rates were reported to improve up to 50% with the introduction of sulfonamides, and further to 80% with the introduction of penicillin (5). The incidence of intracranial complications of otitis media was reported to decline from 2.3% to 0.04% after the use of antibiotics (6). However, complications from otitis media continue to be a problem in developing countries like Nepal.

This study was conducted in Tribhuvan University Teaching Hospital, which is one of the oldest and busiest tertiary referral centers in Nepal’s capital Kathmandu. The hospital also has the highest bed capacity in the country. Therefore, this study intends to be able to shed light on the changing trends of the complications in the twenty-first century in a developing country, Nepal.

A study by Kangsanarak et al. (7) in Thailand found the prevalence of complications from otitis media to be 0.69%. Similarly, in our study, we found this rate to be 0.78%. However, this rate is still high compared to that from developed countries. Samuel et al. (8) found the incidence of extracranial complications to be 0.13%, and Palva et al. (9) reported the incidence of intracranial complications to be 0.04%. In developed countries, rarity of complications limits the experience of the otologist (1).

Before the advent of antibiotics, 52% of the complications were secondary to acute otitis media. With the use of suitable antibiotics, however, complications encountered today are mostly from chronic otitis media (1). In our study, the incidence of complications from acute otitis media was found to be 0.5%, while the incidence of complications from chronic otitis media with cholesteatoma was found to be 5.6%. This difference between the rates of complications from acute and chronic otitis media may be due to the use of antibiotics and the routine vaccination against *Haemophilus influenza* and *Streptococcus pneumoniae*. Chronic otitis media without cholesteatoma is referred to as the safer type of otitis media, but complications may nevertheless occur. Complications in non-cholesteatomatous otitis media usually occur in neglected cases of tubotympanic disease. The incidence of complications in chronic otitis media without cholesteatoma in this study was 0.06%.

The complications of acute and chronic otitis media were highest in the population under 20 years of age (48.28%). Also, 50% of the complications from acute otitis media were seen in patients aged younger than 20 years. This finding of our study is comparable to that reported by Osma et al. (6), where 58% of patients with complication were under 20 years of age. In our study, 74% of intracranial complications were seen in patients under 20 years of age. Samuel et al. (8) reported 74% of intracranial complications occurring in children and young adults in their study. Complications are more commonly seen in children than in adults given the increased frequency of otitis media in children due to immature Eustachian tube, low immunity, the aggressive nature of paediatric cholesteatoma, well-pneumatized paediatric temporal bone where spread of cholesteatoma becomes easy, and greater inflammatory markers in paediatric cholesteatoma (10).

In a study by Singh and Maharaj (5) with 268 patients in 1993, 32% had extracranial complications, 56% had intracranial complications, and 12% had combined extracranial and intracranial complications. This report contrasts with our study where we found 131 (80%) patients with extracranial complications, 18 (11%) with intracranial complications, and 15 (9%) with multiple complications. In 2011, Wu et al. (11) reported that extracranial complications had gradually increased, whereas intracranial complications had gradually decreased during their 22-year study. The decrease in intracranial complications may be due to the early administration of higher generation antibiotics, the widespread use of high-resolution imaging, and the improvement in microsurgical techniques.

The clinician should be vigilant about the possibility of more than a single complication in patients. Mostafa et al. (12) reported two concurrent complications in 54%, and three or more concurrent complications in 44.7% of their 422 patients. Wu et al. (11) had multiple complications in 10% of their patients, which is a finding comparable to that found in our study. Facial palsy was the most common concurrent complication in our

Facial nerve palsy was the second most common intracranial complication in our study. The commonest site of brain abscess was the temporal lobe, followed by the cerebellum. The rate of mortalities from brain abscess was reported by Kangsanarak et al. (7) as 33% and by Osma et al. (6) as 20%. There was no mortality in our study from brain abscess. A multidisciplinary team comprising an otorhinolaryngologist, a neurosurgeon, a critical care physician, an anaesthesiologist, a radiologist and an ophthalmologist is required for the proper management of such a case. Previously, mastoid exploration was recommended to be delayed until the patient recovers after brain abscess drainage. The current recommendation, however, is to perform mastoidectomy in the same session as the brain abscess drainage if the patient can tolerate general anaesthesia (15).

Brain abscess, which is a serious complication, was the most common intracranial complication in our study. The commonest site of brain abscess was the temporal lobe, followed by the cerebellum. The rate of mortalities from brain abscess was reported by Kangsanarak et al. (7) as 33% and by Osma et al. (6) as 20%. There was no mortality in our study from brain abscess. A multidisciplinary team comprising an otorhinolaryngologist, a neurosurgeon, a critical care physician, an anaesthesiologist, a radiologist and an ophthalmologist is required for the proper management of such a case. Previously, mastoid exploration was recommended to be delayed until the patient recovers after brain abscess drainage. The current recommendation, however, is to perform mastoidectomy in the same session as the brain abscess drainage if the patient can tolerate general anaesthesia (15).

Osma et al. (6), Kangsanarak et al. (7), Dubey and Larawin (17), and Lin et al. (18) reported meningitis to be the most common intracranial complication. In our study, meningitis was the second most common intracranial complication. The mortality rate of meningitis in the pre-antibiotic era was 35% and declined to 5% with the use of antibiotics (15). Ibrahim et al. (19) reported the incidence of meningitis from acute otitis media as 13%, and from chronic otitis media as 3%. Early treatment is necessary to reduce mortality and its sequelae. Surgical intervention is recommended after the patient improves with intravenous antibiotics.
Lateral sinus thrombosis comprises 17% to 19% of the intracranial complications (15). High index of suspicion is required, because nowadays the previously described classical clinical presentation is rare due to the use of antibiotics. Magnetic resonance venography should be done to see the patency of the venous sinuses. There were three cases of lateral sinus thrombosis from chronic otitis media with cholesteatoma in our study and all of them coexisted with other complications such as facial palsy, cerebellar abscess and meningitis, mastoiditis, and temporal lobe abscess. There was one mortality in our study, which was a case of lateral sinus thrombosis with facial palsy. The mortality rate of lateral sinus thrombosis was reported as 10% by Samuel et al. (8). The role of exposing the sigmoid sinus with evacuation of the clot is debatable and currently conservative surgery seems to be sufficient (2). Systemic anticoagulants should be used in selected cases only, such as involvement of the sagittal sinus or a persistent rise in intracranial pressure (15).

There were two cases of extradural abscess and one case of subdural abscess in our study. Neurosurgical procedure was performed initially followed by canal wall down mastoidectomy.

The mortality from otitis media is usually secondary to intracranial complications. Mortality rate has reduced from 75% in the pre-antibiotic period to 5% in the antibiotic period in developed countries (14). The mortality rate in our study was 0.6%. The low mortality rate in our study could be due to the lower incidence of intracranial complications compared to extracranial complications, as well as prompt treatment of patients, improved microsurgical techniques and critical care services in our center.

The limitations of this study are its retrospective nature and the disproportion between the sample sizes of the acute and chronic otitis media groups. In the future, prospective studies on the impact of routinely administrated pneumococcal conjugate vaccine in complications from otitis media may be performed.

Conclusion
The incidence of complications due to chronic otitis media with cholesteatoma is higher as compared to that of acute otitis media and chronic otitis media without cholesteatoma. Extracranial complications are common as compared to intracranial complications. However, multiple complications may occur. Otorhinolaryngologists should be aware about the possibility of masking of the symptoms and the absence of classical clinical presentation with the use of antibiotics.

**Ethics Committee Approval:** Ethics committee approval was received for this study from the Institutional Review Committee of Institute of Medicine, Tribhuvan University (Approval Date: January 7, 2020; Approval Number: 278(6-11)E2 076/077).

**Informed Consent:** Informed consent was obtained from the patients who participated in this study.
