What Has Changed in the Diagnosis and Treatment of Colorectal Cancer?

Geçmişe Göre Günümüzde, Kolorektal Kanseri Tanısı, Önlenmesi ve Tedavisinde Ne Değişti?

ABSTRACT

Colorectal cancer (CRC) is the most common malignancy in the gastrointestinal tract. CRC is associated with significant morbidity and mortality in the worldwide. CRC is the third most common cancer-related death in both men and women globally. The overall 5-year survival rate is 50% last decade (1975). Currently this rate is over 75-80%. In this case; early diagnosis, prevention and effective treatment methods were the main factors. Nowadays, Genetic Analysis test, Fecal Occult Blood testing and colonoscopy methods are used in screening. Genetic Analysis testing is the best method for the lead time. In addition, polypectomy was performed in precarious patients and was classified as preventable disease.

Keywords: Colorectum, cancer, early diagnosis, lead time, prevention of cancer

INTRODUCTION

Cancer is a non-lethal genetic disorder in the cell, more simply defined as uncontrolled cell proliferation. The activation of oncogenes, inactivation of tumor suppressor genes, impairment of DNA repair ability, inability to perform apoptosis, reprogramming the cell energy metabolism that has been recently studied, and the protection of the tumor cell from the immune system constitute the basic physiopathology. One or more physiopathological conditions is caused by hereditary, physical, chemical and/or biological (bacteria, virus) factors. Colon is the approximately 150 cm part of the gastrointestinal system between the ileocecal valve and the rectosigmoid corner. It consists of the cecum, ascending colon, transverse colon, descending colon, and sigmoid colon. The rectum is considered as a separate organ today. The nutrition of the colon is provided by the branches originating from the two main arteries of the aorta. The upper mesenteric artery is the midgut artery, it supplies the right half of the colon (a. ileocolic, right colic and middle colic artery). The lower mesenteric artery is the artery of the hindgut, it supplies the left half of the colon (left colic artery, sigmoid artery). These two networks are connected to each other by the arc of riolan. The venous anatomy of the colon is generally similar to the anatomy of the artery. The right colon drains into the portal system through the vena mesenterica superior, the left colon drains into the portal system through the vena mesenterica inferior.
through the vena mesenterica inferior. Likewise, the drainage of the lymphatic system takes place along the arteries and occurs in four main stages; epicolic, intermediate, paracolic and prespinal (paraaortic) lymph node.

**Its Epidemiology and Distribution**

It is the most common malignancy in the gastrointestinal tract. In terms of mortality, it is among the third most common causes of death after lung and prostate cancer. It shows geographic differences throughout the world and its incidence in undeveloped regions is 6.5/7.7 per 100,000 women/men and around 50.9/60.8 in developed regions. The distribution of colon tumors is often seen in the sigmoid colon and then in the cecum.

**Etiology**

Its etiology is not known for certain, but genetic and environmental factors that affect the colon mucosa play a role. In terms of genetic factors, colon cancer is more common in those with familial polyposis or familial adenoma (>90%). It is also known that colon cancer develops without the presence of polyposis [hereditary non-polyposis colorectal cancer (CRC) or Lynch syndrome 1, 2]. It has been suggested that one or more of the adenomatous polyposis coli (APC), p53, deleted in colorectal cancer (DCC), MCC and K-ras genes play a role. When examined in terms of diet, it is known that excessive amounts of meat and fat ingested change the colon flora and establish a ground for cancer. Studies suggesting an increased incidence of colon cancer after cholecystectomy or ureterosigmoidostomy have been conducted, but their accuracy has not been proven. It is known that there is a relationship between inflammatory bowel diseases and colon cancer. In addition, age is an important risk factor for colon cancers. It increases significantly after the age of 50 years. Correct determination of risk factors is important for effective results of community monitoring and screening programs.

**Genetics in CRC screening:** Somatic mutation in adenoma plays a role in the majority of colon cancers and hereditary (germline) mutation in some colon cancers. When mutations occur in more than one gene, it results in cancer. It takes a long time, such as 10-15 years, for a mutation in a normal cell to result in cancer (Sojourn time). Therefore, lead time can be kept much shorter with screening programs. K-, N-, H-ras (especially K-ras) activation of proto-oncogenes, APC which are tumor suppressor genes, DCC and p53 mutation, mutation of mismatch repair (MMR) genes, especially the hMSH2 gene among the MMRs play a major role in the cancerization of colon cells (50%). In addition, hMSH3, 6 and hPMS2 and 3, of the MMR genes, also play a role. Multiple gene mutations are detected by DNA analysis.

**Fecal Occult Blood test (FOBT) in CRC screening:** With the formation of cancer tissue or adenomas reaching a certain size, bleeding occurs into the lumen. In this case, the diagnosis of cancer becomes meaningful after a certain period of time to occur cancer.

**Colonoscopy in CRC screening:** In 20% of cases, it may give false negative results due to insufficient bowel cleansing or inability to visualize the mass.

**Lead time in early diagnosis:** Genetic analysis test > FOBT > colonoscopy.

**Pathogenesis:** The majority of these tumors originate from the glandular epithelium and are adenocarcinoma. It originates in the mucosal epithelium and spreads in the lumen and/or intramural region.

**Classification in CRC:** Two types of cancer are macroscopically seen in the colon. a) “Cauliflower” is often seen on the right side of the colon, b) “ring-structure” is seen on the left side of the colon.

**Clinical Symptoms and Signs**

It is an inapparent disease and gives late symptoms. Initially, it starts with anemia and lower gastrointestinal system bleeding, then progresses as a change in bowel habit (diarrhea, constipation, change in stool characteristics). Non-specific symptoms such as abdominal pain, nausea, tenesmus, and weight loss are observed. Obstruction signs are observed in patients with more advanced stage. In other words, the clinical picture varies depending on the location, macroscopic structure, stage and complications of the tumor. Tumors located on the right side of the colon present with anemia, and those located on the left side with signs of obstruction. In developed countries, while 87.9% of the cases were admitted to the emergency service with obstruction in the 1925s (stage 4), today there has been a decrease in admission to the emergency services with obstruction (76-80%). This has been achieved with the effective use of diagnostic methods and conscious society. However, a significant decrease is not observed in undeveloped societies.

**Screening and Diagnosis**

Cancer screenings are for detecting diseases at an early stage, thus reducing the incidence of advanced stage patients and reducing mortality. The delay in diagnosis of colon cancer is still an important problem in today’s underdeveloped societies. The biggest factor in this situation is the education and social status of the patients. Tests for colon cancer screening include FOBT, genetic analysis test and structural examination (colonoscopy, capsule endoscopy, double contrast barium graphy, computed tomographic (CT) colonography or
in these cases, metastasis often occurs in the liver (70-80%) 1. If metastasis is present, the tumor mass is resected en-bloc after tumor with lymphatics that it drains (R 0, radical resection) and anastomosis for intestinal continuity are applied. Today, endoscopic muco-submucosal resection method is used in developed countries for early stage tumors.  For cases with regional tumors: If the tumor has invaded neighboring organs, the tumor mass is resected en-bloc after neoadjuvant chemoradiotherapy. For patients with local tumors: With conventional, laparoscopic or robotic methods, the resection of the primary tumor with lymphatics that it drains (R 0, radical resection) and anastomosis for intestinal continuity are applied. Today, endoscopic muco-submucosal resection method is used in developed countries for early stage tumors. For cases with regional tumors: If the tumor has invaded neighboring organs, the tumor mass is resected en-bloc after neoadjuvant chemoradiotherapy.

Prognosis: In developed countries, while the five-year survival rate was 50% in the past years (1975), this rate is 75-80% today13. In developing countries, patients are still diagnosed at a late stage, which decreases the patient’s five-year survival rate12,13.

CONCLUSION

CRC is the third most common cause of death from cancer worldwide14. Although colon cancer is more common in developed countries compared to underdeveloped countries15,16, today, it can be prevented by screening programs in developed countries. While cure can be achieved with early diagnosis and effective surgery, unfortunately it is still an important health problem in undeveloped countries. In undeveloped countries, the disease can be brought to a preventable level with the education of individuals and effective implementation of screening programs.
