**ABSTRACT**

Myeloid sarcoma (MS) is an aggressive tumor characterized by leukemic proliferation with or without mature myeloid cells, which can be seen anywhere in the body except bone marrow (1). MS is a hematological malignancy, rarely encountered as a soft tissue mass in the extramedullary system called granulocytic sarcoma or chloroma (2-4). Although MS can develop in any part of the body, it is frequently seen in bone, lymph nodes, soft tissue, and skin (1, 5). Breast tissue is a rare region for MS development, and only 3% of cases with MS in breast tissue were reported in the Mayo Clinic series (6, 7). The development of MS of the breast tissue after bone marrow transplantation (BMT) in patients with acute myeloid leukemia (AML) is remarkable (8).

**Key Points**

- Myeloid sarcoma (MS) is an aggressive tumor.
- Breast tissue is a rare region for MS development.
- The development of MS of the breast tissue after bone marrow transplantation (BMT) in patients with acute myeloid leukemia (AML) is remarkable.
- If a breast mass is detected, the diagnosis should be supported by immunohistochemistry and biopsy.
- Systemic treatment should be started as soon as possible.

**Introduction**

Myeloid sarcoma (MS) is an aggressive tumor characterized by leukemic proliferation with or without mature myeloid cells, which can be seen anywhere in the body except bone marrow (1). MS is a hematological malignancy, rarely encountered as a soft tissue mass in the extramedullary system called granulocytic sarcoma or chloroma (2-4). Although MS can develop in any part of the body, it is frequently seen in bone, lymph nodes, soft tissue, and skin (1, 5). Breast tissue is a rare region for MS development, and only 3% of cases with MS in breast tissue were reported in the Mayo Clinic series (6, 7). The development of MS of the breast tissue after bone marrow transplantation (BMT) in patients with acute myeloid leukemia (AML) is remarkable (8).

**Case Presentation**

A 31-year-old female presented to the General Surgery Department Breast and Endocrine Unit with the complaint of a palpable mass in both breasts. Seventeen years ago, the patient underwent surgery and chemotherapy due to osteosarcoma in the left ankle. Six years ago, she underwent a bilateral breast fibroadenoma excision, and four years ago, she underwent an excision due to phyllodes tumor in the right breast. Four years ago, bone marrow biopsy, peripheral smears, and hematological tests during postoperative controls were performed and they showed abnormal findings. After she was diagnosed with AML, BMT was performed. One month ago, she had a total thyroidectomy due to a malignant tumor in the left thyroid lobe. She experienced a postoperative pathology of papillary thyroid carcinoma with AML infiltration and follicular variant. During that period, she had masses in both breasts. On physical examination, 4–5 cm masses were palpated on the bilateral breasts. On the recent breast ultrasonography (USG), it was observed that the patient had masses in the lower outer quadrant of the right breast, whose borders were...
ambiguous. A 2.5 cm residual phyllodes tumor with a heterogeneous structure and an approximately 1 cm fibroadenoma with a slightly faint border at 3 o’clock were noted in the left breast. In the same period, fluorodeoxyglucose-18 (FDG-18) [FDG- positron emission tomography/computed tomography (PET)/CT] imaging showed that the mass in the right breast maximum standardized uptake values [(SUV<sub>max</sub>) = 3.9] had activity involvement. There were no other positive findings in the PET/CT scan of the patient. Since the patient had a systemic disease, PET/CT imaging was performed after breast USG. This does not normally fit the breast imaging sequence and it is an exception for this patient. Due to the coronavirus disease 2019 (COVID-19) pandemic, there was a disruption in the follow-up. The control PET/CT imaging was performed after six months showing massive lesions of 4 cm in the right breast and 5 cm and 1.5 cm in the left breast (SUV<sub>max</sub> = 9) and a 1 cm (SUV<sub>max</sub> = 3.7) increase in the metabolism areas in both axilla (Figure 1). It was decided to perform a breast and axilla Tru-Cut biopsy. The results of the biopsies were interpreted MS containing diffuse blastic cell infiltration. Microscopic images of diffuse blastic cell infiltration in breast tissue with haematoxylin and eosin stain (H&E) are shown in Figure 2. When the blastic cells were examined immunohistochemically, they showed diffuse strong cytoplasmic staining with cluster of differentiation-45 (CD45), CD34, CD117, and human leukocyte antigen-DR (HLA-DR) and focal strong cytoplasmic staining with myeloperoxidase (MPO). Immunohistochemical staining images of breast tissue showing blast cells positive for CD45, CD34, CD117, HLA-DR, and MPO are shown in Figure 3.

The patient was evaluated in the oncology council. Due to the aggressive spread, a BMT and systemic chemotherapy were planned. The mass in the patient’s breast did not need a palliative resection. The patient was followed up after the planned therapies.

**Discussion and Conclusion**

Although MS is an extramedullary hematological malignancy, in which myeloid cells show various degrees of maturation, it is frequently seen in patients with previously diagnosed myeloid leukemia (9, 10). According to the World Health Organization, MS is diagnosed based on three classes: blastic (consisting of myeloblasts), immature (consisting of myeloblasts and promyelocytes), and differentiated (consisting of promyelocytes and more mature neutrophils) (8). Although MS can develop in any part of the body, the development of MS of the breast is extremely rare. For this reason, patients with MS in the breast are often misdiagnosed as having lobular breast carcinoma, non-Hodgkin lymphoma, or small-round-blue-cell tumor (11). The first area where extramedullary relapse occurs after stem cell transplantation is the breast, and relapse can occur 2–73 months after transplantation (average 17 months) (8). MS may occur as a unilateral or bilateral breast mass, but it usually does not cause nipple retraction (2, 12-14). Although there was no specific finding of MS in the breast when examining the studies, case reports emphasize the findings of irregular, spiculated, angular or unclear margins, and posterior shadowing (7, 15). MS diagnosis can be supported by MPO, CD34, CD 43, CD 117, and CD 68 (12). Specific CD markers can be very useful in diagnosis. CD 117, CD 68, and CD 43 are positive in most cases, and CD 45 is reactive in 75% of the cases (12).

There is no consensus on the treatment of MS of the breast, but surgical resection (lumpectomy or mastectomy) with systemic chemotherapy is generally recommended (7, 8). Simultaneous radiotherapy is controversial (8). Disease-free survival is predicted between three and twelve years with systemic chemotherapy (8). In light of the literature, the diagnosis was supported by MPO, CD 34, CD 43, CD 117, and CD 68 (12). Specific CD markers can be very useful in diagnosis. CD 117, CD 68, and CD 43 are positive in most cases, and CD 45 is reactive in 75% of the cases (12).

Figure 1. Axial paranchimal fused PET/CT image showing massive lesions of 4 cm in the right breast and 5 cm and 1.5 cm in the left breast (SUV<sub>max</sub> = 9) and 1 cm (SUV<sub>max</sub> = 3.7) increase in metabolism areas in both axilla

PET/CT: Positron emission tomography/computed tomography

Figure 2. Microscopic images of diffuse blastic cell infiltration in breast tissue with haematoxylin and eosin stain (H&E). a) Diffuse blastic cell infiltration in breast tissue (H&E x100). b) Diffuse blastic cell infiltration in breast tissue (H&E x200). c) Diffuse blastic cell infiltration in breast tissue (H&E x400)
In this case report, we described the management of a patient with MS of the breast, which is a rare tumor. It should be kept in mind that MS may develop in the breast after BMT in patients with AML and those patients should be followed up using breast ultrasound. If a mass is detected, the diagnosis should be supported by immunohistochemistry and biopsy, and systemic treatment should be started as soon as possible.
